Internalized homophobia as a partial mediator between homophobic bullying and self-esteem among youths of sexual minorities in Quebec (Canada)

Homofobia internalizada como mediador parcial do bullying homofóbico e autoestima entre jovens de minorias sexuais em Quebec (Canadá)

Abstract Verbal/psychological homophobic bullying is widespread among youths of sexual minorities. Homophobic bullying has been associated with both high internalized homophobia and low self-esteem. The objectives were to document verbal/psychological homophobic bullying among youths of sexual minorities and model the relationships between homophobic bullying, internalized homophobia and self-esteem. A community sample of 300 youths of sexual minorities aged 14 to 22 years old was used. A structural equation model was tested using a nonlinear, robust estimator implemented in Mplus. The model postulated that homophobic bullying impacts self-esteem both directly and indirectly, via internalized homophobia. 60.7% of the sample reported at least one form of verbal/psychological homophobic bullying. The model explained 29% of the variance of self-esteem, 19.6% of the variance of internalized homophobia and 5.3% of the verbal/psychological homophobic bullying. The model suggests that the relationship between verbal/psychological homophobic bullying and self-esteem is partially mediated by internalized homophobia. The results underscore the importance of initiatives to prevent homophobic bullying in order to prevent its negative effects on the well-being of youths of sexual minorities.

Key words Internalized homophobia, Homophobic bullying, Self-esteem, Sexual minority

Resumo A homofobia verbal/psicológica (bullying homofóbico) é comum entre jovens de minorias sexuais. Está associada com homofobia internalizada e baixa autoestima. Os objetivos foram documentar o bullying homofóbico verbal/psicológico entre jovens de minorias sexuais e modelar a relação entre o bullying homofóbico, homofobia internalizada e autoestima. Foi utilizada uma amostra da comunidade com 300 jovens de minorias sexuais, na faixa etária entre 14 a 22 anos. Foi testado um modelo de equação estrutural usando um estimador não linear, robusto, implementado no Mplus. O modelo postula que o bullying homofóbico tem impacto na autoestima, direta e indiretamente, via homofobia internalizada. Os resultados apontaram que 60,7% da amostra relataram pelo menos uma forma de bullying homofóbico verbal/psicológico. O modelo explicou 29% da variância da autoestima, 19,6% da variância da homofobia internalizada e 5,3% do bullying homofóbico verbal/psicológico. O modelo sugere que a relação entre bullying homofóbico verbal/psicológico, assédio moral e autoestima é parcialmente mediada por homofobia internalizada. Os resultados sublinham a importância de iniciativas para prevenir o bullying homofóbico, evitando os efeitos negativos sobre o bem-estar dos jovens de minorias sexuais.

Palavras-chave Homofobia internalizada, Bullying homofóbico, Autoestima, Minoria sexual
Introduction

Results from studies conducted in the USA and Canada have shown that homophobic bullying is widespread among sexual minority youths. Indeed, up to 87% of lesbian, gay, bisexual, transgender, or questioning (LGBTQ) youths have been victims of at least one form of homophobic bullying. Although homophobic bullying can take various forms (e.g., psychological or verbal, physical, sexual, etc.), some studies have suggested that psychological or verbal bullying is the most common form of homophobic bullying. Among LGBTQ senior high school students, humiliation and/or teasing (M = 52.1%, F = 48.3%) and damage to reputation (M = 46.2%, F = 51.7%) are the three most common forms of homophobic bullying.

Although homophobic bullying is prevalent among LGBTQ youths, they do not represent a homogenous group and the specific forms or correlated victimization experienced may differ considerably. Rates of homophobic bullying vary according to gender identity and age. Many studies suggest that sexual minority boys are more likely to report verbal homophobic bullying based on sexual orientation compared to their female counterparts. Taylor et al.’s results suggest that trans-identified youths are at higher risk of suffering from verbal homophobic bullying than LGB boys and girls. However, as they get older, youths tend to report lower rates of both physical and verbal homophobic bullying.

According to the classical definition of the sociometer hypothesis, self-esteem refers to "an internal, subjective index or marker of the degree to which the individual is being included versus excluded by other people." As argued elsewhere by Leary, however, it is more appropriate to conceptualize self-esteem as a signal of one’s relational value. Relational value can be defined as "the degree to which a person regards his or her relationship with another individual as valuable, important, or close." Therefore, the function of self-esteem could be to notice any impairment in the inclusionary status or relational value of each individual. Hence, as a consequence of real or perceived bullying, youths may experience a feeling of exclusion and a deterioration of their perceived relational value, resulting in lower self-esteem. Such results have been reported independently of sexual orientation. Homophobic bullying could also have substantial deleterious effects on the self-esteem of LGBTQ youths. LGBT reporting homophobic bullying are more likely to report lower self-esteem. Yet, few studies have tried to evaluate which form of homophobic bullying was specifically related to self-esteem. Nevertheless, a study conducted with sexual minority males in their early adulthood revealed that verbal harassment and discrimination based on sexual orientation were associated with low levels of self-esteem, but not physical homophobic bullying. This association between homophobic bullying and self-esteem appears to be of special interest.

Sexual minorities are confronting specific challenges related to their sexual minority status, such as acquiring a positive identity while experiencing social stigma and exclusion. Internalized homophobia (IH), defined as "the application of anti-LGB stigma to the self," is one possible consequence of intimidation based on non-exclusive heterosexuality. There are few studies that have assessed the impact of peer bullying on IH among youths. Nevertheless, Willoughby et al. have shown that homophobic bullying among GLB and queer youths and young adults is associated with a negative LGB identity, a concept reflecting IH, needs for privacy and acceptance regarding sexual orientation, and difficulties in accepting one’s sexual orientation. Furthermore, recent studies have revealed that heterosexist harassment, rejection and discrimination is related to IH among adult gay men, bisexual men, questioning men, and lesbian women. Thus, homophobic bullying not only impairs self-esteem, but it may also increase IH among LGBTQ youths. Also, a recent review by Szynanski et al. revealed that sexual minority men and women reporting high levels of IH are more likely to report low levels of self-esteem, suggesting that homophobic bullying impacts self-esteem both directly and indirectly, through IH.

Both lower self-esteem and IH have been associated with negative outcomes. Recent studies, including meta-analysis, have shown that both factors increased psychological distress, depression and anxiety. Lower self-esteem has also been associated to physical dating violence victimization among males, suicidal ideation, suicidal attempt and long-term impacts such as mental and physical health problems, criminal convictions, and fewer economic prospects in later adult life. IH also appears to be a strong predictor of posttraumatic stress symptoms among LGBTQ youths, even after controlling for variables such as verbal and physical homophobic bullying, stressful life events, gender, etc.
Given the importance of self-esteem for mental health and well-being among sexual minority youths and the centrality of homophobic bullying in youths’ lives, the current study aims to document verbal/psychological homophobic bullying among LGBTQ youths and young adults and to model the relationships between homophobic bullying, IH and self-esteem. The hypotheses are: 1) that males will show higher rates of homophobic bullying than females, and that transidentified youths will show higher rates of homophobic bullying than males; and 2) that bullying impacts self-esteem both directly and indirectly, via IH and that these relationships hold when controlling for gender and age (see Figure 1).

**Method**

Data for this study are drawn from the Quebec Youths’ Romantic Relationships survey. The questionnaire included self-reported measures on a variety of dimensions relevant to the study of victimization and took approximately 40 minutes to complete. The research ethic boards of the Université du Québec à Montréal approved this project. Participants agreed to participate on a voluntary basis by signing a consent form, either on paper or electronically.

**Sample and procedure**

Data were collected among youths aged 14 to 22 through a web-based survey targeting Quebec LGBTQ youths. Two main recruitment strategies were used. A general strategy was Facebook ads targeting youths aged 14-22 with interests in sexual minorities. Specific strategies consisted of publicizing the survey through both active and passive online recruitment (publicity banners on websites targeting LGBTQ youths and using mailing lists identified by key informants) and snowballing. These participants were assigned a stratum based on their region of residence; a common cluster belonging to take into account the non-independence of the observations among the community sample; and a sample weight based on age, gender and sexual orientation (attraction and behavior) as reported in two representative Quebec studies of youths31 and Hébert et al. (ongoing study). The current study was composed of 300 non-exclusively heterosexual participants.

**Figure 1. Hypothesized mediation model of HB on SE through IH.**

Note: SE = Self-Esteem. IH = Internalized Homophobia. HB = Homophobic Bullying. W vs. M = Women compared to Men. T vs. M = Transidentified compared to Men.
Variables

Sociodemographics. Data were collected on age (in years), sex at birth and transidentity. Transidentity was questioned using the following item: When their sex at birth and their gender identity (sense of belonging to one sex) do not match, some people define themselves as a trans person (transgender, transsexual, trans-identified). Do you consider yourself as a trans person? Sex at birth and transidentity were combined to create three categories: men (M), women (W), transidentified participants (T). Dummy variables comparing women and trans to men were created (W vs. M, T vs. M).

Psychological/verbal homophobic bullying (HB). Participants were questioned on three specific forms of psychological/verbal prejudice, based on Chamberland et al. study. The question was: During the last 6 months, how frequently did you experience the following situations because people think that you might be gay/lesbian/bisexual or trans or because you are gay/lesbian/bisexual or trans? Three forms of homophobic bullying were covered: exclusion and rejection (HB1); humiliation (HB2); damage to the reputation (HB3). For each prejudice, a five anchors nominal scale was created: Never (1), Rarely (2), Sometimes (3), Often (4), and Always (5). These three forms of intimidation correspond to psychological homophobic bullying/teasing. The three items showed a high internal consistency (χ² = .87).

Self-esteem (SE). Self-esteem was evaluated with 4 items from the Self-Description Questionnaire (SDQ). Participants had to choose the answer that best describes how they feel concerning the following statements: Overall, I have a lot to be proud of (SE1). In general, I like myself the way I am (SE2). I like the way I look (SE3) and When I do something, I do it well (SE4). Response options were: False (0), Mostly false (1), Sometimes false/Sometimes true (2), Mostly true (3), and True (4). The scale showed a high internal consistency (χ² = .85).

Internalized homophobia (IH). Internalized homophobia was measured with four items from the Lesbian, Gay, and Bisexual Identity Scale (LG-RIS). The instruction was: For each of the following statements, mark the response that best indicates your experience as a lesbian, gay, or bisexual (LGB) person. Please be as honest as possible in your responses. The four items were: I would rather be straight if I could (IH1), I wish I were heterosexual (IH2), I am glad to be an LGB person (IH3), and My life would be more fulfilling if I were heterosexual (IH4). The response options were: Strongly disagree (1), Disagree (2), Somewhat disagree (3), Somewhat agree (4), Agree (5), Strongly agree (6). The Cronbach’s alpha for this sample was good (α = .82).

Analyses

Rates of prejudice based on sexual orientation according to gender were estimated with their 95% confidence interval. A structural equations model (SEM) was tested with the Mplus software, v.7.11, using a nonlinear, robust estimator (WLSMV) and taking into account the complex sample (stratification, clustering and sampling weights). The lowest value of the covariance coverage, measuring the proportion of non-missing data in the covariance matrix, was 0.760. Missing data were handled with the full information maximum likelihood (FIML) implemented in Mplus. The χ² test was used to detect potential misspecifications in the hypothesized model. A non-significant χ² value, a RMSEA value < 0.05, and values of CFI and TLI > 0.90 were considered to indicate an adequate fit of the model.

Results

Participants (n = 300) were aged between 14 and 22 years old (M = 17.9, SD = 2.02). More women (63.7%) than men (36.3%) participated in the study. The majority of the participants were from urban agglomeration (86.3%). Regarding sexual attraction, 73.7% of the participants described themselves as homosexual, 15.3% as bisexual; 7.7% reported a predominantly heterosexual attraction and 3.3% reported being unsure. Thirteen (13) percent of the participants identified themselves as trans or questioning their gender identity.

Table 1 presents the rates of homophobic bullying by gender identity. About half (48.4%) of the participants suffered from damage to reputation or reported at least one episode of humiliation (48.0%), and a third (34.3%) have felt excluded or rejected. Sixty-one (60.7) percent of the sample reported at least one form of verbal/psychological homophobic bullying. There were no statistically significant differences between homophobic bullying rates according to gender identity, although women tend to report higher rates.

Frequencies for the three forms of verbal/psychological homophobic bullying under study are presented in Table 2. Among youths who report-
ed at least one episode of homophobic bullying, 7.6 to 11.2% indicated that they were "often" or "always" victimized.

The theoretical model described in Figure 1 was tested. The $\chi^2$ statistic for the hypothesized models was 79.66 (df = 65), $p$-value = .104, suggesting that the tested model did not differ significantly from the data. The two non-significant paths were removed (W vs. M $\rightarrow$ HB and T vs. M $\rightarrow$ HB). The revised model (see Figure 2) fit the data well ($\chi^2 = 79.67$, df = 67, $p = 0.138$). The good fit of the model was also supported by

Figure 2. Revised model (standardized coefficients).

Note: SE = Self-Esteem. IH = Internalized Homophobia. HB = Homophobic Bullying. W vs. M = Women compared to Men. T vs. M = Transidentified compared to Men. The numbers on the straight, single-headed arrows are path coefficients. The small arrows pointing to HB, IH and SE are residual variances, reflecting the proportion of variance that cannot be explained by the independent variables. All coefficients are standardized. All coefficients were significant at the 5% level, except for Age $\rightarrow$ IH and W vs. M $\rightarrow$ SE (in gray).
an averaged RMSEA value of 0.025 as well as CFI and TLI values over 0.98.

The model explained 29% of the variance of self-esteem, 19.6% of the variance of internalized homophobia and only 5.3% of the homophobic bullying. The signs of all the coefficients were in the expected direction. The total (direct and indirect) effect of homophobic bullying on self-esteem was negative and significant. The model suggests that the relationship between homophobic bullying and self-esteem is partially mediated by internalized homophobia among sexual minority youths.

Effects of gender are worth noticing. Internalized homophobia was higher among women and transidentified compared to men. The total effect of women gender on self-esteem was non-significant (unstandardized coefficient = -0.09, s.e. = 0.15, p = 0.55), while only the direct effect for transidentified gender was significant (unstandardized coefficient = -0.90, s.e. = 0.11, p < 0.001).

Discussion

As previous researchers have shown, the results of the current study revealed that verbal/psychological homophobic bullying among LGBTQ is widespread. Nearly half of youths reported damage to reputation or humiliation because of their sexual orientation, 10% of which mentioned experiencing this form of bullying often or more. Contrary to many studies, we did not find a significant relationship between gender and homophobic bullying. Possible explanations are the general high rate of homophobic bullying in all groups and the lack of power due to sample size of gender subgroups. Another study among Quebec youths showed similar rates of homophobic bullying prevalence and no differences according to gender.

Age was the only variable predictive of homophobic bullying. As reported by others, as youths become older, they tend to experience, or at least report, less homophobic bullying. This is consistent with the fact that bullying in general (not exclusively homophobic bullying) seems to be more prevalent among 6th through 8th grade students compared to 9th and 10th grade students. The final model explained only 5% of the variance of homophobic bullying. Future studies might include other variables such as disclosure of sexual orientation, gender nonconformity as well as socioeconomic and cultural characteristics of the social environment as predictors of homophobic bullying among sexual minority youths to better understand its determinants.

As hypothesized, homophobic bullying impacts self-esteem both directly and indirectly through internalized homophobia. In our study, participants who were victims of homophobic bullying were more likely to report low levels of self-esteem. These results suggest that homophobic bullying is likely to generate a general signal of rejection and of threat regarding one’s relational value, and thus decreases self-esteem, independently of the internalization of the homophobic stigma. Therefore, it is possible that the mere fact of being bullied, notwithstanding the homophobic nature those detrimental behaviors, is a good indicator to the self that one’s relational status could be impaired, resulting in low levels of self-esteem.

Similar to results found by other studies presented above, we found that LGBTQ youths who were bullied because of their sexual orientation also reported higher levels of IH. Feinstein et al. argued that their results are coherent with the psychological mediation framework of Hatzenbuehler. Hatzenbuehler’s framework postulates that stigma related stressors, such as bullying, can lead to group specific processes, such as internalized homophobia. Thus, it can be argued, as suggested by Allport, that when a minority group suffers from discrimination and disparagement, some individuals may react by identifying themselves with the ideas of the majority group, hence developing a sense of self-hate. This “mechanism is involved in cases where the victim instead of pretending to agree with his ‘better’ actually does agree with them, and sees his own group through their eyes” (quote marks and italics are from the original text, p150).

In the current study, youths who were bullied because of sexual minority status may have interpreted these prejudices as signs of societal disapproval and condemnation of sexual minority behaviors and status, thus internalizing the anti-LGBTQ stigma.

IH was also predictive of low self-esteem. It is possible that the internalization of homophobic stigma leads LGBTQ youths to fear future rejection, impairing their sense of relational value and their self-esteem. Transidentified youths reported higher levels of IH and lower levels of self-esteem than men. One interpretation is that transgendered youths were more victimized than other sexual minority youths in domains unmeasured in the current study (e.g., bullying based on...
gender nonconformity), and that they were intimi-
dated for a greater length of time. That woman also reported higher internalized homo-
phobia than men was surprising and cannot be ex-
plained by the variables included in this study. Clearly future investigations are necessary to as-
certain these interpretations.

Limitations

Some limitations of the study must be stated. Firstly, the cross-sectional nature of the data pre-
vents any conclusion on the causal relationship between variables. Nevertheless, a longitudinal
study revealed that peer victimization was predic-
tive of later self-esteem levels, suggesting that
the direction of the core relationship under study
(homophobic bullying and IH) is plausible. Sec-
ondly, since we used a community-based sample,
it is difficult to assess the representativeness of
our sample. Gay and bisexual men, who are more
likely to be bullied according to many studies, were
also less likely than women to participate in the
current study. As for transidentified people, they
are difficult to recruit and their small number in
the sample leads to a lack of statistical power to
detect differences. Thirdly, beside sociodemo-
graphic variables, the current model included no
determinants of homophobic bullying. Similarly,
we evaluated only emotional and psychological
forms of homophobic bullying. To better under-
stand the phenomenon of bullying based on sex-
ual orientation and its consequences, other stud-
ies should try to include variables that could pre-
dict homophobic bullying (e.g. gender noncon-
formity), and evaluate different forms of ho-
phobic bullying (e.g. physical, sexual, etc.). Fi-
nally, all measures were self-reported. It is there-
fore possible that bias were present in the data.
For example, it is possible that those with high IH
remember more homophobic bullying episodes
than those with low IH.

Notwithstanding these limitations, the
present study offers relevant data to sustain a
better understanding of the realities of verbal/
psychological homophobic bullying in LGBT
youth and the relationships between homopho-
bic bullying, IH and self-esteem. Our results clear-
ly underscore the importance of initiatives to pre-
vent homophobic bullying in order to prevent its
negative effects on the well-being of LGBTQ.

Collaborations

M Blais, J Gervais and M Hébert participated
equally in all stages of preparation of the article.

Acknowledgments
