Abstract. This paper proposes a new approach to the classification of Developmental States (DS) based on their public efforts to foster human development. We conceptualize DS within a multidimensional framework that includes three main dimensions (economic, social and democratic), and run a hierarchical cluster analysis for 112 countries in order to build a multidimensional taxonomy of DS. We propose a country-classification and characterize three country-groups with different developmental public efforts: *i*) the human development States; *ii*) the unbalanced developmental States and *iii*) the non-developmental States. Our multidimensional taxonomy offers a more complex understanding of the variety of public efforts devoted to promote human development, thus overcoming the restricted –economical– conception of DS, which is mainly focused to the East Asian region.

Key Words: developmental states; multidimensional taxonomy; social equality and democratic participation; welfare states; economic growth.

UNA TAXONOMÍA MULTIDIMENSIONAL DE ESTADOS DESARROLLISTAS

Resumen. Este trabajo propone un nuevo marco para clasificar a los Estados Desarrollistas (ED) basado en sus esfuerzos para mejorar el desarrollo humano. Se conceptualiza a los ED en un marco multidimensional con tres dimensiones principales (económica, social y democrática) y se realizó un análisis de clúster jerárquico para 112 economías con el fin de construir dicha taxonomía. Se propone una clasificación por país y se clasifican tres grupos en función de sus esfuerzos desarrollistas: *i*) los Estados de desarrollo humano; *ii*) los Estados desarrollistas desbalanceados y *iii*) los Estados no-desarrollistas. La taxonomía multidimensional ofrece un entendimiento más complejo de la variedad de esfuerzos públicos para promover el desarrollo humano, superando así la concepción –económica– restringida de los ED prevaleciente en la región del Este Asiático.

Palabras clave: Estados de desarrollo humano; taxonomía multidimensional; igualdad social y participación democrática; Estados de bienestar social; crecimiento económico.

Clasificación JEL: F43; I31; I38; O15; R13.

1. INTRODUCTION

The concept of Developmental States (DS) gained notoriety during the 1980s and 1990s as a successful explanation for the “East Asian economic miracle”. It was argued that the region’s rapid economic growth and the modernization of its productive structures were the result of a series of successful industrial policies focused on boosting exports, technology and innovation, paired with fiscal and financial incentives to enhance economic productivity and competitiveness (Johnson, 1982; Amsden, 1989; Wade, 1990).

Drawing on this literature, some authors have recently revisited the DS concept in order to explain the recent socio-economical successes of some emerging economies. In this context, some authors identify the presence of emerging DS in some developing countries (Malik, 2013), but also in developed countries such as the United States (Block, 2008).

Moreover, one feature stands out among its antecedents: the inclusion of new dimensions of development beyond the traditional economic approach, thus evolving from an economic unidimensional concept to a multidimensional one. This new approach includes both a social dimension (Kwon, 2005 and 2009, Sandbrook *et al.*, 2007; Evans and Heller, 2013) and a democratic dimension (Robinson and White, 1998; Edigheji, 2010). Hence, some authors currently talk about “human development States” as an ideal category of this new multidimensional conception where DS are defined, beyond income growth, by their ability to expand human opportunities and capacities (Evans and Heller, 2013; Malik, 2013; De la Cruz, 2017; Hsu, 2018; Nem Singh and Ovadia, 2018).

Inevitably, this new multidimensional conception of the DS challenges the traditional dichotomy of either being a DS or not, and thus opens the door for exploring the different typologies of DS derived from a multidimensional conception. This is the main objective of this paper, which offers an international and multidimensional taxonomy of DS in order to evaluate public efforts to promote human development around the world.

To that end this paper is structured into five sections, including this introduction: firstly, we review the theoretical evolution from an unidimensional to a multidimensional conception of DS. Secondly, we describe the methodology used to build an international taxonomy of DS by means of a hierarchical cluster analysis. Then we explain the main results of the classification. Finally, we draw the main conclusions and explore the implications of using a multidimensional taxonomy of DS.

2. CONCEPTUALIZATION OF DEVELOPMENTAL STATES: FROM UNIDIMENSIONALITY TO MULTIDIMENSIONALITY

Traditionally, DS has been conceptualized as States that experience rapid economic growth (in terms of income per capita) and productive structure modernization. This economical conception of DS has endured over two centuries, from the seminal contributions of Hamilton and List, to the most recent studies on the East Asian economic miracle (Amsden, 1989; Wade, 1990; Woo-Cumings, 1999).¹ In part, this economical conception of DS was associated with the hegemony of the economic theory on the conceptualization of “development”, simplifying the concept mainly to “income growth” (Evans and Heller, 2013).

However, in the second half of the 20th century, with the emergence of the multidisciplinary field of “development studies”, several researchers questioned the economical conception of DS and stressed the need for wider analytical approaches (Seers, 1969; Streeten, 1984; Sen, 1999). This long road was initiated through the “basic needs approach” and it gained maturity and integrity with the “human development approach”. Human development is understood as a process of expansion of the freedoms acquired through an interaction between individual capacities and the opportunities provided by the environment, or, in Amartya Sen’s terms:

The expansion of freedom is viewed in this approach both as the primary end and as the principal means of development. Development consists of the removal of various types of unfreedoms that leave people with little choice and little opportunity of exercising their reasoned agency. The removal of substantial unfreedoms, it is argued here, is *constitutive* of development (Sen, 1999, Preface xii).

Following Sen’s definition, we can derive that the focus on the expansion of freedom implies two break ups from the traditional economic conceptualization of development:

Firstly, the human development approach understands income increases as a “means” to the expansion of human freedoms, not as an “end” itself. As a result, income growth becomes one of the possible drivers of development, but it is not the only one; many others exist, such as educational and health improvements (social capital) and democratic participation (political capital),

¹ For an extensive review of the literature on DS see Routley (2012) and De la Cruz (2014).

for instance. From this perspective, development has a broader nature and determining factors, transitioning from a process of economic capital accumulation to a process of human capital accumulation and redistribution. As a result, new dimensions emerged to explain different paths to increasing individual freedoms, thus transitioning from unidimensionality to multidimensionality in the conception of the development process.²

Secondly, and as a result of the previous argument, the human development approach questioned the traditional wisdom on the relation between the different channels (dimensions) that lead to development. Traditionally, the economic thought understood these relationships as a trade-off (accumulation *vs.* redistribution) or merely as independent variables (accumulation and political regime), but did not consider positive feedbacks between them. However, several recent empirical studies have tested these relationships, demonstrating that, at least, the trade-off is not the only possible direction, and that in many cases positive loops can take place (“multiplier effect”), thus opening the door to multidimensional-reinforced –instead of substitutive– approaches in the pursuit of human development.³

Finally, should be mentioned that the proposals on the multidimensionality of development are not limited to the human development approach. Notable progress has been made from other areas, such as gender approaches (Boserup, 2007) and environmental approaches to sustainable development (Redclift and Springett, 2015). These approaches have extended the multidimensional concept of development, integrating new and complementary dimensions into the general framework of the expansion of freedoms and capabilities.

Among others, the sustainable development approach –intimately linked to the challenges facing the Planet– has gained notoriety. As it affects economic, political, social and cultural dynamics, sustainable development must be tackled from a transversal perspective. Accordingly, some approaches to the developmental State have been developed from this environmental

² For an extensive discussion on the scope and multidimensionality of human development see, among many others, Nussbaum (2001) and Alkire (2002).

³ See, among others, Ostry and Berg (2011) and Berg *et al.* (2012) on the positive relationship between social equality and economic growth in the long run; Besley and Kudamatsu (2006 and 2007), McGuire (2010) and Gerrig *et al.* (2012) on the positive relationship between democracy and human development; Ostry *et al.* (2014) on the positive effect of social redistribution on economic development; Hanushek and Woessmann (2008 and 2012) on the positive effect of cognitive development spending on economic growth; and Ranis *et al.* (2000 and 2006) on the positive effect of human development on economic growth. There is still no clear evidence of the direction of the relationship between democracy and economic growth (Barro, 1996; Doucouliagos and Ulubasoglu, 2008).

perspective (and are connected, in a broader sense, with the globally widespread proposals of *Green New Deals*, i.e. the structural transformation of the economy from an environmentally sustainable perspective) (Wong, 2012; Swilling *et al.*, 2016).

In this sense, and from a conceptual perspective, we draw on the concept of human development proposed by Sabina Alkire, that incorporates in its definition the sustainable development approach as follows:

Human development aims to expand people's freedoms –the worthwhile capabilities people value– and to empower people to engage actively in development processes, on a shared planet. And it seeks to do so in ways that appropriately advance equity, efficiency, sustainability and other key principles (Alkire, 2010, p. 24).

Therefore, the human development approach has redefined the conception of development, offering a broader understanding that highlights the importance and complexity of multidimensionality. Consequently, the framework linked to the conceptualization of the DS has also shifted towards a new multidimensional conception of DS, in line with the human development approach (Leftwich, 1995; Robinson and White, 1998; Kwon, 2005 and 2009; Sandbrook *et al.*, 2007; Evans, 2008; Edigheji, 2010; Hayashi, 2010; Malik, 2013; Evans and Heller, 2013).

The concept of “multidimensional DS” implies a broader approximation to State interventions in order to achieve human development. Although the economic dimension remains central, new dimensions have been added for State interventions to foster human capacities and opportunities. In particular, there is a wide consensus on the need to include two new dimensions: social equality and democratic participation (Routley, 2012). These two dimensions entail both new public structures (such as the institutions typical of welfare State) and new relationships between public institutions, the civil society and the private sector (Hsu, 2018). Moreover, new instruments and incentives are also considered in these two dimensions in order to provide social redistribution and democratic participation (Evans and Heller, 2013).⁴

The economic dimension of this new conception of multidimensional DS remains similar to the traditional economical conception of DS. However, as

⁴ Initially the environmental sustainability dimension was also considered. However, due to methodological reasons, mainly linked to the lack of homogeneous and reliable data at the international level, it was ruled out. For a further explanation on this issue, see De la Cruz (2017).

some authors have pointed out, bilateral (Shadlen, 2005) and global (Wade, 2003) trade agreements, as well as global trade networks (Yeung, 2014), have placed important limitations on the industrial policies of DS, particularly on their respective incentives on taxation, trade and finance. Some authors argue that the economic dimension has been progressively restricted to research, innovation and education linked to industrial policies (Mazzucato, 2013), while maintaining traditional institutional quality and performance (Evans, 1995).

In relation to the social dimension, public structures are any type of structure that form the welfare State (*i.e.* all public social policies that have a direct impact on improving the skills and opportunities of citizens).

Within this framework, the relationships between civil society agents and the welfare state bureaucracy are particularly relevant, as well as the public instruments and incentives directed towards the efficient provision of social services (Sandbrook *et al.*, 2007; Malik, 2013).

Finally, the democratic dimension involves all public structures linked to the provision of political rights, expression and participation, which thus allow for the expansion of freedoms associated with these rights. This approach breaks away from the traditional conception of semi-authoritarian DS, focusing instead on transparency, accountability, participatory policies and political rights (Evans and Heller, 2013).

3. METHODOLOGY: A CLUSTER ANALYSIS OF MULTIDIMENSIONAL DEVELOPMENTAL STATES

Traditionally, the study of DS has been focused on countries with accelerated levels of economic growth, in line with the unidimensional concept of economic development. Methodologically, these analyses consisted of case (country) studies and comparative (regional) studies, mainly focused on the East Asian region. As a result, they offered deep explanations of the functioning patterns of public structures and their link to economic development.

However, methodological limitations arise when using a multidimensional concept of DS. Including new dimensions and variables in the analysis complicates both the qualitative analysis and the assessment of the traditional dichotomy –a State is either a DS or not– as it opens a wide variety of possibilities in which States can be successful in certain dimensions but not in others. Therefore, this multidimensional approach opens the door to multiple types of DS according to their different multidimensional efforts/

performances. This, in turn, implies that all countries are potential objects of analysis, thus increasing the complexity associated with comparative qualitative methodologies.

In contrast with the previous studies, we pursue a comparative analysis that includes a large number of countries with a limited set of explanatory variables in order to build an international “taxonomy” of DS. Thus, we expand our analytical universe beyond developing countries by also including developed countries, as we want to assess public efforts on human development promotion across the world. Besides –as Block (2008) argued–, developed countries may present a developmental public approach that has not yet received the proper attention.

In particular, we opted to perform a cluster analysis, which is a numerical technique that is suitable for classifying a sample of heterogeneous countries in a limited number of groups, each of which is internally homogeneous in terms of the similarities between the countries that comprise it. Ultimately, the goal of cluster analysis is to provide classifications that are reasonably “objective” and “stable” (Everitt *et al.*, 2011): “objective” in the sense that the analysis of the same set of countries by the same numerical methods produces similar classification; and “stable” in that the classification remains similar when new countries are added.

Specifically, hierarchical cluster analysis allows us to build a taxonomy of States with heterogeneous developmental profiles in order to divide them into a number of groups so that: *i*) each country belongs to one –and only one– group; *ii*) all countries are classified; *iii*) countries of the same group are, to some extent, internally “homogeneous”; and *iv*) countries of different groups are noticeably dissimilar. The advantage of this procedure is that the “association structure” between countries can be discerned, which –in our analysis– facilitates the identification of the key development characteristics of each cluster.

Cluster analysis is structured in two main stages. First, the selection of the clustering variables, which includes defining the dimensions and selecting the corresponding variables (proxies). And second, the selection of the clustering toolkit. Four guiding principles are applied when selecting the appropriate variables for each dimension: *i*) segment differentiation, *ii*) low correlation between variables, *iii*) optimal relation between sample size and cluster variables; and *iv*) high quality and availability of data.

Segment differentiation is assured first through the selection of three different dimensions. Two sub-dimensions in each dimension are also contemplated (see Table 1): “innovation” and “institutional quality” for the economic

Table 1. Dimensions, indicators and sources

<i>Dimensions</i>	<i>Subdimensions</i>	<i>Proxies</i>	<i>Sources</i>	<i>Years</i>
Economic development	Research, development and innovation	% Public spending on R+D+i over GDP	World Bank (2016a) UNESCO (2016) and OECD (2016)	2014 or closest available year
	Institutional quality	Government effectiveness	World Bank (2016b)	2014 or closest available year
Social development	Education	% Public spending on education over GDP	World Bank (2016a) and UNESCO (2016)	2014 or closest available year
	Health	% Public spending on health over GDP	World Bank (2016a)	2014 or closest available year
Democratic participation and good governance	Quality of democracy	Polity IV	Center for Systemic Peace (2016)	2014 or closest available year
	Participation and inclusion	Voice and accountability	World Bank (2016b)	2014 or closest available year

Source: own elaboration.

dimension, following the economic institutional literature on DS (Evans, 1995; Mazzucato, 2013); “education” and “health” for the social dimension, following the human development approach (Malik, 2013); and “democratic quality” and “voice and accountability” for the democratic dimension (Evans and Heller, 2013).

It is worth mentioning that cluster analysis works better with simple indicators rather than synthetic ones, so we were ultimately faced with a choice between input and output indicators.⁵ On one hand, input variables reflect the “public effort” to promote development, but they do not necessarily lead to “public performance” (this will depend on many factors). On the other hand, output variables work the other way around. Following the conceptual discussions on DS (Mkandawire, 2001; Vu, 2007; Fritz and Menocal, 2007) and our conceptualization of multidimensional DS (which is focused on public efforts devoted to promote human capacities and opportunities), we opt for “input variables” as proxies of public efforts.⁶

⁵ For a methodological justification on the preference for simple over synthetic indicators when running cluster analysis see Dolnicar and Grün (2008).

⁶ For an extensive discussion on the tension between development structures (input indicators) and development outcomes (output indicators), see Mkandawire (2001); Vu (2007) and Fritz and Menocal (2007).

Finally, to assure segment differentiation we run the Pearson correlation test in order to check for problematic correlations between pairs of variables (see Appendix 1).

The test shows no problematic correlations between variables.⁷ Moreover, in terms of a reasonable relationship between sample size and the number of clustering indicators, we apply Formann's (1984) rule that recommends a minimum sample size of 2^n , where n equals the number of clustering variables. In our case, with a sample of 112 countries, the maximum n is equal to six.

The second step is the selection of the clustering toolkit. We run a hierarchical clustering through an agglomerative clustering procedure, that is, a bottom-up construction of a tree-like structure in the course of the analysis. The main issue concerning this stage is the measurement of similarities/dissimilarities between pairs of countries. As we have both positive and negative values in our dataset, we choose the squared Euclidean distance, which is the square root of the sum of the squared differences in the variable values. And as we mix variables with different scales we also standardize the variables.⁸

Regarding the selection of the cluster algorithm, given the type of data used in our analysis (six continuous variables), three possibilities are the nearest neighbour method, the furthest neighbour method and the Ward's method (Everitt *et al.*, 2011; Sarstedt and Mooi, 2014). Since there is no objective criterion for selecting the most appropriate method and the selection depends largely on the interpretability of the final results, we choose the method proposed by Ward (1963), in which the fusion of two clusters is based on the size of an error sum-of-squares criterion.

The objective at each stage is to minimize the increase in the total within-cluster error sum of squares. In practical terms, the Ward's method has been proven to be especially suitable for building clusters with similar sizes, when no outliers are present (Everitt *et al.*, 2011; Sarstedt and Mooi, 2014).

The next step is to decide on the number of DS groups (that is, the number of clusters to retain from the data). This decision is based on three different criteria: the agglomeration schedule (see Appendix 2), the dendrogram (see Figure 2) and the variance ratio criterion (see Table 2).

⁷ According to Sarstedt and Mooi (2014), problematic correlations appear over 0.9.

⁸ Regarding the standardisation method, we use the "range -1 to 1" which is deemed to be preferable than other methods "in most situations" (Sarstedt and Mooi and, 2014, p. 247). The analysis was conducted using SPSS software.

The agglomeration schedule displays the clusters combined at each stage and the distances at which clusters merge (see Appendix 2). This schedule is used to determine the optimum number of country groups. By plotting these distances against the number of clusters we can identify a distinct break or “elbow” (that is, where an additional combination of two clusters occurs at a greatly increased distance). The number of clusters prior to the merge is the most probable solution.

Thus, and despite the high number of countries included in the graph, the scree plot shows a distinct break due to the increase in distance when switching from a three to a four-cluster solution (see Figure 1).

The dendrogram graphically displays the distances at which countries (and clusters of countries) are joined (see Figure 2).

The dendrogram is read from left to right: vertical lines are countries joined together; their position indicates the distance at which the mergers take place. This graph provides guidance in terms of the number of groups to retain, showing that a three –cluster solution is appropriate.

Figure 1. Elbow graph

Source: own elaboration.

Figure 2. Dendrogram

Source: own elaboration.

Finally, Calinski and Harabasz (1974) proposed a more precise and objective method for determining the optimum number of clusters. The “variance ratio criterion” (VRC) recommends choosing the number of clusters that maximizes the ratio between the overall between-cluster variation and the overall within-cluster variation with regards to all clustering variables (that is, a good clustering yields groups of countries with small within-cluster variation but high between-cluster variation). In our case, this suggests that the optimum number of clusters is three (see Table 2).

Table 2. Variance ratio criterion (VRC)

<i>Num. clusters</i>	VRC_k	<i>Estadístico w_k</i>
2	798.88	..
3	710.41	-135.52
4	486.42	133.84
5	396.25	133.54
6	439.63	..

Source: own elaboration.

Therefore, using the three procedures (agglomeration schedule, dendrogram and VRC criterion) we determine the optimum number of clusters to be three. Before comparing the characteristics of these three clusters, we evaluate which variables are more influential in discriminating across countries. This step is particularly important as cluster analysis sheds light on whether the groups of countries are statistically distinguishable (that is, whether the clusters exhibit significantly different means in the development indicators).

It should be mentioned that the cluster solutions of our analysis are reasonably “robust”. As recommended by Sarstedt and Mooi (2014), we verify the robustness of the cluster analysis with the following three-step check: first, we evaluate the stability of the results by using different clustering procedures, distance measures and standardization methods on the same data and test whether these yield similar taxonomies. However, one should bear in mind that –as noted by Everitt *et al.* (2011) –, among many others– results often change even when the cluster solution is adequate, so some degree of variation is expected when changing the cluster procedure. Secondly, we change the order of the countries in our data set and re-run the analysis to check the

results' stability. The results should not depend on the order of the data set, unless there are outliers that influence the results. And thirdly, we replace one of the proxies –the *Voice and accountability* variable– with an alternative variable (*Growth rate*) for the same dimension.

The first check shows moderate variations in the results. In particular: *i*) changing the clustering procedure from Ward to the “link between groups” only affects 38 out of the 112 countries; *ii*) changing the distance measure from square Euclidian distance to Chebyshev distance only renders 1 differently classified country (Cuba); and *iii*) changing the standardization method from range -1 to 1 to the simple z standardization only renders 37 differently classified countries. The second check shows no variation in the results: changing the order of the countries in the data set does not affect the classification. Finally, the substitution of *Voice and accountability* for *Growth rate* only changes the classification of four countries.

All in all, cluster analysis (as a multivariate statistical analysis) implies certain limitations in various aspects that we must take into consideration. Three limitations are worth mentioning:⁹

First, the need to synthesize a complex and multidimensional concept, such as the public intervention of a developmental State, with a limited number of indicators implies a certain conceptual reductionism. This limitation is further reinforced by the methodological requirement of using simple *versus* synthetic indicators.

Second, including the developed countries in our taxonomy enlarges the analytical universe and allows us to build a complete international taxonomy, thus reflecting the whole range of developmental public interventionism patterns across the globe. However, this increase in the sample size also implies some analytical drawbacks, as it dilutes some interesting intra-cluster differentiations, especially among developing countries. We try to sort this out by extending the scope of the taxonomy in order to analyze sub-cluster patterns.

Third, in the particular case of the World Bank's “institutional quality indicator”, some authors criticize the “biases” of its design, its statistical sources and the “construct validity” of the indicator (Thomas, 2010). In any case, at present day this is the best and most comprehensive indicator available for the measurement of institutional quality with an internationally comparable database.

⁹ For an extensive discussion on the limitations of this methodological approach, see De la Cruz (2017).

**4. RESULTS: A TAXONOMY FOR
MULTIDIMENSIONAL DEVELOPMENTAL STATES**

Our cluster analysis produces a taxonomy of 112 States that are classified into three different groups (see Figure 2 and Appendix 3). A precise interpretation of the three clusters involves examining the cluster centroids (that is, the clustering variables' average values of all countries in a certain cluster). This comparative procedure enables us to analyse the data on the basis of the grouping variable's values. According to Table 3 the three DS clusters can be described as follows:

Table 3. Centroids per cluster

<i>Clusters</i>		<i>Innovation</i>	<i>Gov. effect.</i>	<i>Education</i>	<i>Health</i>	<i>Polity IV</i>	<i>Voice</i>
Cluster 1 (N = 24)	Mean	2.41	1.50	5.54	9.79	9.71	1.29
	St.dev	0.83	0.33	1.14	2.29	0.62	0.31
Cluster 2 (N = 64)	Mean	0.49	-0.04	4.76	6.62	7.61	0.05
	St.dev	0.41	0.68	2.05	2.08	2.28	0.59
Cluster 3 (N = 24)	Mean	0.35	-0.53	4.34	5.84	-4.63	-1.12
	St.dev	0.41	0.46	2.17	1.95	2.93	0.46
Total (N = 112)	Mean	0.87	0.18	4.84	7.13	5.44	0.06
	St.dev	0.96	0.92	1.95	2.52	5.77	0.94

Source: own elaboration.

- Human development States (Cluster 1). This cluster includes 24 developed countries (18 european countries, plus Australia, Canada, Israel, Japan, New Zealand, South Korea and the United States) that make the highest efforts on all three dimensions and their corresponding six proxies. It is worth noting that the dendrogram shows a subsequent formation of two sub-clusters, which are mainly differentiated in terms of their innovation efforts. Thus the first sub-cluster is composed of 10 countries with the highest relative investments in R+D+i (Israel, South Korea, Finland, Sweden, Denmark, Austria, Germany, Australia, Japan and Slovenia), whereas the second sub-cluster has relatively lower innovation efforts (which includes, among others, France, Spain, Portugal and Ireland).

- Unbalanced developmental States (Cluster 2). This cluster is composed of 64 developed and developing countries. In particular, all Latin American countries (except Cuba), some South and East European countries and some African and Asian States are in this group. These States have low economic and social efforts with four indicators slightly under the overall average (*Innovation, Government effectiveness, Education and Health*). However, their *Democratic quality* is above the overall average, while *Voice and accountability* remains low but close to the average. Furthermore, the dendrogram suggests a subdivision into two sub-clusters: countries above the average on the social and democratic dimensions (Uruguay, Italy, South Africa, Poland and Greece) and those below the average (Jamaica, Mongolia, Kenya, Ukraine, Namibia and Bolivia) (see Appendix 3). There are, however, six countries that could be considered as outliers of this cluster: Singapore and Malaysia make important efforts on both economic indicators, while Brazil and Russia focus their efforts on innovation capacities, and Moldova and Lesotho make exceptional public efforts on health and education policies.
- Non-developmental States (Cluster 3). This cluster includes 24 States, all of them located in Asia, Africa and East Europe (non EU members). These States show anemic public efforts on the economic, democratic and social dimensions with all six proxies below the overall average. Moreover, this cluster can be divided into three sub-clusters: countries with the worst figures on the democratic dimension (mainly autocracies or low density democracies such as Iran, Egypt or China);¹⁰ countries with slightly less negative figures on the democratic dimension (such as Jordan, Morocco and Thailand); and the particular case of Cuba, which makes an outstanding investment effort on health and education.

This taxonomy shows that State developmentalism from a human development perspective is not only a phenomena associated to the East Asian States. Furthermore, while the traditional North-East Asian countries are included in the “human development States” cluster (such as Japan and South Korea) the other South-East Asian DS are included in the other two categories. On one hand, Singapur, Malaysia and Indonesia are among the “unbalanced States”, in spite of their remarkable performance on the economic dimension, as they

¹⁰ China is also the country in cluster 3 with the highest effort on innovation.

make limited efforts on the social and democratic dimensions. On the other side, Thailand is considered a “non developmental States” as its public efforts are under the average in the economic and democratic dimensions.

Moreover, we explore whether the public efforts (“inputs”) across DS clusters are finally transformed in developmental performance (“outputs”). Obviously, different levels of efficiency in public interventions can result on very different development outcomes. To test so we compute the average Human Development Index (HDI) for each of the three clusters.

The results show –as expected– a close correlation between inputs and outputs: “human development States” (C1) have the highest HDI, followed by the “unbalanced developmental States” (C2) and the “non-developmental States” (C3) (see Table 5). In particular, as the HDI does not include democratic indicators, it is not surprising that C2 and C3 have similarly low HDI averages.

Table 4. Average HDI per cluster

Source: own elaboration based on UNDP (2016).

Finally, it is worth mentioning that the differences between clusters are significant. According to the one-way ANOVA analysis, which allows us to compare the differences across the cluster centroids, the six variables included in the classification are statistically significant (see Table 5).

The size of the *F* statistics shows the relation between the overall between-cluster variation and the overall within-cluster variation and, therefore, it is a good indicator of the relevance of each variable for identifying groups of countries. According to this criterion, the variable with the greatest discriminating power in the classification is *Democratic regime*, followed by *Innovation* and *Voice and accountability*. By contrast, the variables with lowest relative importance are *Education*, *Health* and *Government effectiveness*.

Table 5. One-way ANOVA

5. CONCLUSIONS

Analysing DS from a human development approach widens the scope beyond the economic policies in the East Asian region to the complexities of an international and multidimensional development landscape. Thus, the conceptualization of DS needs to shift from a restricted –economical– concept to a multidimensional –“development studies”– one. In our case we opt for a conceptualization of DS that includes two new dimensions, apart from economic development: social progress and democratic governance.

Consequently, we understand that the scope of the analysis should not be restricted to countries that are focused on promoting income growth (the “traditional” DS), but it should also include those States which promote opportunities and capacities to their citizens, thereby generating a complex progress of “human development”. This is why we analyse a wider analytical universe that includes both developed and developing countries, and we run a hierarchical cluster analysis that allows us to build a reasonable taxonomy for 112 different States.

The results of our analysis show that the democratic and economic indicators are the two main drivers of our multidimensional taxonomy. We end up with three different groups:

- i)* The human developmental States, which include 90 percent of OCDE Members and are characterized by “sound” democratic institutions, broad Welfare States and important economic efforts.
- ii)* The unbalanced human development States, which are mainly located in Latin America and East Europe; they are characterized by low economic and social efforts but acceptable democratic quality.
- iii)* The non-developmental States, which are mainly autocracies and low-density democracies around the world with low economic, social and democratic efforts.

As expected, “human development States” do not only make the greatest efforts to promote development but they also have the highest performance in terms of their HDI. In contrast, “unbalanced developmental States” and “non-developmental States” have significantly lower HDI performances. Thus, expanding Block’s (2008) argument on the presence of DS in developed nations, we suggest that from an input/output multidimensional conceptualization, most developed nations show typical DS features. On the other hand, while acknowledging significant progress in some dimensions, we refuse the recent literature argument raising the possibility of emerging DS in some developing nations (Malik, 2013; Evans and Heller, 2013).

All in all, our multidimensional taxonomy offers a more complex understanding of the variety of public efforts devoted to promote human development, thus overcoming the restricted (economical) conception of DS, which is mainly focused to the East Asian region. For example, Japan and South Korea –two countries generally considered as DS– fall in cluster 1 (human DS), whereas Singapur, Malaysia and Indonesia belong to cluster 2 (unbalanced DS) due to their most restricted efforts on the social and democratic dimensions.

Appendix 3. Countries/states per cluster and sub-cluster

Human developmental states (cluster 1)

Sub-cluster C.1.1: Israel, South Korea, Finland, Sweden, Denmark, Austria, Germany, Australia, Japan, Slovenia.

Sub-cluster C.1.2: United Kingdom, Ireland, Spain, Portugal, Luxembourg, Czech Republic, Estonia, Norway, New Zealand, Belgium, France, Canada, Netherlands, United States.

Unbalanced developmental states (cluster 2)

Sub-cluster C.2.1: Mali, Mozambique, Ecuador, Guatemala, Nepal, Nicaragua, Paraguay, Burundi, Honduras, Gabon, Russia,* Venezuela, Bolivia, Lesotho, Moldova, Botswana, Ghana, Jamaica, Kenya, Kyrgyzstan, Mongolia, Namibia, Senegal, Tunisia, Armenia, Sri Lanka, Zambia, Madagascar, Pakistan, Congo Rep.

Sub-cluster C.2.2: Argentina, Peru, Philippines, Romania, Indonesia, India, Turkey, Bulgaria, Panama, Trinidad and Tobago, Macedonia, Ukraine, El Salvador, Colombia, Mexico, Georgia, Malaysia,* Singapore,* Chile, Cyprus, Lithuania, Poland, Croatia, Latvia, Mauritius, Brazil,* Serbia, Costa Rica, South Africa, Hungary, Italy, Slovak Rep, Uruguay and Greece.

Non-developmental states (cluster 3)

Sub-cluster C.3.1: Belarus, Iran, Vietnam, Egypt, Gambia, Ethiopia, Tajikistan, Sudan, Azerbaijan, Kazakhstan, Lao, Kuwait, Oman, Saudi Arabia, China.*

Sub-cluster C.3.2: Jordan, Morocco, Thailand, Burkina Faso, Tanzania, Cambodia, Uganda, Togo.

Sub-cluster C.3.3: Cuba.*

Note: * exceptional cases: Cuba, Lesotho, Moldova, China, Singapore, Malaysia, Russia, China and Brazil.
