**Abstract:** Snake venoms are widely used as laboratory tools for studies of physiological, pharmacological and toxicological mechanisms. Venoms used here are rich sources of several classes of proteases that act on factors of the coagulation cascade, fibrinogenolysis and fibrinolysis, altering the hemostatic processes, and phospholipases A<sub>2</sub> which are involved mainly in inflammatory and clotting processes. Natural products such as essential oils are made up of active ingredients with wide application in the food, pharmaceutical and cosmetic industries. Thus, this study evaluates the essential oils from *Mentha viridis* and *Mentha pulegium* on coagulation, fibrinogenolysis and degradation of azocasein, induced by *Bothrops* sp and *Lachesis muta muta* venoms. These oils were achieved by hydrodistillation and presented, respectively, as the main constituents linalool (40.70 %), carvone (13.52 %) and  $\alpha$ -terpinene (8.56 %); pulegone (50.01 %), menthol (31.90 %) and menthone (16.56 %). The essential oils were previously incubated with *Bothrops alternatus* venom, for two different times, then plasma was added and time was recorded. The *M. viridis* oil presented greater anticlotting potential. Meanwhile, the *M. pulegium* oil presented anticlotting or proclotting activity dependent on the dose tested. The incubation time also influenced the effect of the oils on the coagulation time. At azocaseinolytic assay, the oil from *M. pulegium* reduced the activity for all evaluated venoms. The highest inhibition was of 39.99 %; on activity induced by *B. jararacussu*, *M. viridis* reduced the activity in 57.72 %. On *B. moojeni*, the major inhibition observed was of 74.67 %. The fibrinogenolysis induced by *B. moojeni* venom was totally inhibited by both oils in the evaluated proportions. The results show the presence in oils of protease inhibitors, considering serine and metalloproteases (acting on clotting factors or with hemorrhagic activity), as well as phospholipase A<sub>2</sub> (enzymes involved in inflammation and clotting processes) inhibitors of wide application in medical and biotechnology areas.

**Key words:** *Bothrops*; *Lachesis*; protease inhibition; essential oil; natural compounds; antiophidian properties.

Fernandes Silva, L., Aparecida Braga, M., Araújo Espósito, M., Souza Cesar, P. H., & Marcussi, S. (2019). Inhibition by essential oils of *Mentha viridis* and *Mentha pulegium* (Lamiaceae) in proteolysis, fibrinogenolysis and coagulation caused by venomous snakes. *Revista de Biología Tropical*, 67(4), 999-1009.

Essential oils are described as a complex mixture of volatile substances with oily consistency resulting from plant secondary metabolism (Simões et al., 2007). Bandoni and Czepak

(2008) found that the chemical composition of essential oils is changed by varying the proportions of their constituents or by transforming one constituent into another. These changes

occur according to the chemotype, environmental factors and also with the development of the plant.

According to Bakkali, Averbeck, Averbeck, and Idaomar (2008) the major constituents of essential oils may be responsible for biological activity; however, the action of essential oils can also be attributed to the synergistic or antagonistic action of their different components. The plant species that constitute the genus *Mentha*, belonging to the Lamiaceae family (Dimitri, 1980) are widely cultivated on five continents, especially in the temperate and sub-temperate regions of the world (Wang, Yu, Liu, Liang, & Li, 2013).

The essential oils from species of the genus *Mentha* have a high commercial value, because they present the monoterpene menthol in its constitutions, being this compound widely used in the pharmaceutical, cosmetic, personal hygiene and food industries (Khanuja, Shasany, Srivastava, & Kumar, 2000; Santos, Schneider, Bizzo, & Deschamps, 2012). In this perspective the evaluation of the essential oils as to their effects on the proteases and phospholipases A<sub>2</sub> that act in the processes like blood coagulation, inflammation and fibrinogenolysis, as well as their direct action on the blood clotting cascade, would increase the knowledge of these natural products and direct them to new commercial applications.

Snake venoms are complex mixtures which 95 % of the dry weight are protein components mainly represented by enzymes (e.g. proteases, phospholipases and L-amino acid oxidases) (Matsui, Fujimura, & Titani, 2000). Snake venoms present a variety of pharmacologically active substances, which induce pronounced effects such as inflammation and changes in hemostasis (Gutiérrez & Rucavado, 2000).

Snake venom proteases can act by breaking on different protein substrates such as components of cell membranes, blood and tissues proteins and those that make up the basal lamina (Markland, 1998; Baldo et al., 2010). Other studies also report the action of metalloproteases and phospholipases on cells and molecules that integrate the hemostatic system

(Escalante, Rucavado, Fox, & Gutiérrez, 2011; Bernardoni et al., 2014; Sharon, Trabi, & Richards, 2016), as well as the mechanisms by which these classes of toxins act in the blood coagulation cascade. Some proteases act on factors V, VIII, IX, X, XIII, prothrombin, fibrinogen and/or fibrin, altering the fibrin formation and fibrinogenolysis processes (Takeda, Takeya, & Iwanaga, 2012). Phospholipases A<sub>2</sub> have also been described with direct action on factors II, VII, X of the coagulation cascade, or with indirect action on the coagulation process once their catalytic action result in the generation of lysophospholipids (Sajevic, Leonardi, & Krizaj, 2011).

Brazilian folk medicine is very rich in the description and use of plants to combat the various effects caused by ophidian accidents (Marcussi et al., 2007; Carvalho et al., 2013; Guimarães et al., 2014). Considering the wide variety of catalytic and toxic-pharmacological activities carried out by venoms, numerous studies have made use of these and their isolated toxins as laboratory tools of great value in the scientific field. These tools have in vivo, in vitro and in silico application to evaluate the action of inhibitors, mainly natural ones, prospecting their possible effects on enzymes, homologous to those of venoms, present in animal organisms, including humans (Estêvão-Costa, Diniz, Magalhães, Markland, & Sanchez, 2000; McCleary & Kini, 2013).

However, scientific studies that explore the pharmacological properties of plant compounds are poor in discussions about the action mechanisms of these enzymatic inhibitors, especially on human proteases and phospholipases, involved in digestion processes, cell death, tissue regeneration, inflammation and several other processes of great relevance in the development and treatment of pathologies. In this context, the aim of the present study was to characterize the essential oils of *Mentha viridis* L. and *Mentha pulegium* L. through protease and phospholipase inhibition assays, as well as inhibiting blood plasma coagulation, using CaCl<sub>2</sub> or venom to induce the formation of the clot.

## MATERIALS AND METHODS

### Collection and identification of plants:

*Mentha viridis* and *Mentha pulegium* leaves samples were collected in the Federal University of Lavras - UFLA on a mild day without precipitation. The plants were identified and incorporated into the collection of the ESAL Herbarium in the Department of Biology of UFLA - MG, under the registration numbers 27122 (*M. pulegium* L.) and 27123 (*M. viridis* L.).

**Extraction of essential oil:** The extractions were performed with 150 g of each plant species for 3 L of water. Leaves of the two *Mentha* species were weighed and submitted to hydrodistillation process in a modified Clevenger apparatus, adapted to a 6 L round bottom flask, for 2 h, to obtain the hydrolate. The hydrolate was centrifuged at 965.36 g for 10 min. The essential oil was collected (3.81 ml of *M. pulegium* oil and 2.28 ml of *M. viridis* oil) and stored at 12 °C, protected from light (ANVISA, 2010). The extraction of the essential oils was done in triplicate. The yield for the essential oils of *M. pulegium* and *M. viridis* were 2.54 % and 1.52 %, respectively, on a moisture free basis. The chemical characterization of the essential oils of *M. viridis* and *M. pulegium* was previously published by Silva et al. (2015).

**Snake venoms:** The crystalline crude venoms were commercially purchased from the serpentarium Bioagents (Batatais-SP). The venoms were weighed and dissolved in phosphate buffered saline (PBS, pH 7.4).

**Human Blood for clotting assays:** The peripheral blood from three volunteers (10 ml of each volunteer) was used after free informed consent; the volunteers did not present disease symptoms and reported not having used prescription drugs for at least 30 days prior to collection. The volunteers' plasma was obtained by centrifugation and mixed to obtain a pool, used in the assays. This study was approved

by the Committee of Ethics in Research with Humans of UFLA and filed under the number 17935713.8.0000.5148.

**Effects on clotting:** To induce clot formation, a calcium chloride solution ( $\text{CaCl}_2$ ), 50  $\mu\text{L}$  at 100 mM, previously standardized as minimum clotting dose (responsible for inducing coagulation of 200  $\mu\text{L}$  of citrated plasma in a time interval between 3 and 5 min) and 0.4  $\mu\text{g}$  of *Bothrops alternatus* venom, previously standardized as minimum clotting dose, were used.

The coagulation assay was performed according to Mourão et al. (1996), with modifications. For the assay with  $\text{CaCl}_2$  the essential oils from *M. pulegium* and *M. viridis* (0.15; 0.30; 0.60; 1.2; 2.4  $\mu\text{L}$ ) were incubated with  $\text{CaCl}_2$  for 5, 10, 15, 20 or 30 minutes at 37 °C, with subsequent addition of citrated plasma or incubated with the plasma with subsequent addition of  $\text{CaCl}_2$ .

For *B. alternatus* venom coagulation assay, the essential oil from *M. pulegium* or *M. viridis* and PBS in the same volumes were submitted to previous incubations under the same conditions with the *B. alternatus* venom or citrated plasma. Controls containing only plasma +  $\text{CaCl}_2$ , plasma + essential oil and plasma + venom were performed. The reactions were timed and the results presented in minutes that preceded the formation of a rigid clot.

### Proteolytic activity on azocasein:

**Solid medium:** The proteolytic activity in solid medium was evaluated according to Gutiérrez, Avila, Rojas, and Cerdas (1988). The medium was prepared with incorporation of the azocasein, adapting concentrations described by Markland (1998) for evaluation of the caseinolytic activity in liquid medium, as described by Oliveira, Simão, Trento, César, and Marcussi (2016).

The azocasein was dissolved in Tris-HCl (pH 9.6), under slight agitation and, added to the medium at 45 °C. Samples of the essential oils of *M. pulegium* and *M. viridis* (0.60, 1.2, 2.4, and 4.8  $\mu\text{L}$ ) were preincubated at 37 °C for 15 min with *B. jararacussu*, *B. moojeni*,

*B. alternatus* or *Lachesis muta muta* venoms. The azocaseinolytic activity was quantified by measuring the diameter of the halos formed in the medium.

**Liquid medium:** The proteolytic activity in liquid medium was evaluated according to Markland (1998). Different volumes of *M. pulegium* and *M. viridis* essential oils (0.6 and 1.2 µl) were incubated with 50 µg of the *B. jararacussu* or *B. moojeni* venoms and 100 µg of the *B. alternatus* or *L. muta muta* venoms. Incubation volumes were completed to 200 µl with 50 mM Tris-HCl. Samples remained at 37 °C for 15 min, then the casein solution was added and a new incubation was performed for more 30 minutes. Acetic acid 50 % was added to interrupt enzymatic activity, the samples were centrifuged at 900 g for 10 min and the solutions supernatant were read at 450 nm. A unit of azocaseinolytic activity corresponds to an increase of 0.001 in absorbance measured at 450 nm under the reaction conditions defined by the method.

**Fibrinogenolytic activity:** For this activity, the essential oils from *M. pulegium* and *M. viridis* in the volume of 0.60 µl were incubated with bovine fibrinogen (60 µg) at the times of 5, 15, and 30 min. The same volume of oils and incubation times were also used to previous incubations with *B. moojeni* or *L. muta muta* (40 µg) venoms (30 min) with subsequent addition of fibrinogen and incubation for another 2 h at 37 °C.

Reactions were stopped by the addition of 5 µl of bromophenol blue solution [0.05 M Tris-HCl, pH 8.0, containing 10 % (v/v) glycerol, 10 % (v/v) mercaptoethanol, 2 % (w/v) sodium dodecyl sulfate (SDS) and 0.05 % (w/v) bromophenol blue] and incubation in boiling bath for 5 min. The samples were analyzed by electrophoresis in 12 % polyacrylamide gel in the presence of SDS (SDS-PAGE). Controls containing only fibrinogen were also performed.

Possible interactions between the molecules present in the essential oils and fibrinogen were considered through the test with pre-incubation of bovine fibrinogen (60 µg)

and essential oils (0.60 µl) for different times. On the other hand, the inhibitory potential of oils on the fibrinogenolytic enzymes present in the venoms was also evaluated with subsequent addition of each venom (*L. muta muta* and *B. moojeni*).

**Statistical Analysis:** The results were presented as the mean of the triplicates ± standard deviation obtained in three independent assays. The significance of the difference between the means was determined by the analysis of variance, followed by Tukey's test when the treatments were compared with the control (R Core Team, 2012). The results were considered statistically significant when  $P < 0.05$ .

## RESULTS

Incubation of the essential oil of *M. pulegium* with  $\text{CaCl}_2$  proceeding with subsequent addition of the plasma (Fig. 1A) resulted in an increase in coagulation time mainly for the oil volume of 1.2 µl. However, *M. viridis* oil, in all evaluated volumes, induced a reduction in coagulation time reaching values lower than the control, performed only with  $\text{CaCl}_2$ , presenting pro-clotting effect (Fig. 1A).

Another assay was carried out by incubating the essential oils of *M. pulegium* and *M. viridis* (0.15, 0.30, 0.60, 1.2, and 2.4 µl) with plasma for 5 min, followed by addition of  $\text{CaCl}_2$ . In the presence of *M. pulegium* oil, an increase in the coagulation time was observed, characterizing anticoagulant activity. However, a decrease in the coagulation time was observed to *M. viridis* oil, when compared to the control containing only  $\text{CaCl}_2$ , characterizing pro-clotting activity.

To verify the potential of the essential oils in altering the coagulant activity induced by proteases present in the *B. alternatus* venom, tests were also carried out with previous incubation (10 and 20 min) of oils (0.15, 0.30, 0.60, 1.2, and 2.4 µl) with the venom (5 µg), proceeding with plasma addition and timing. At 10 min incubation time, *M. pulegium* and *M. viridis* oils in the volume of 0.30 µl

presented a greater anticoagulant potential, while in the volume of 0.15 µl, *M. pulegium* oil showed pro-clotting effects (Fig. 1C). It was also verified in this assay that larger volumes of essential oils (0.60, 1.2, and 2.4 µl) resulted in pro-clotting activity, with coagulation times lower than the control containing only venom (data not shown). For 20 min incubation time, *M. pulegium* oil presented anticoagulant activity in the volumes of 0.15 and 0.30 µl (Fig. 1C).

The incubation of the essential oil of *M. viridis* with the *B. alternatus* venom and subsequent addition of the plasma resulted in anticoagulant activity for all volumes and times evaluated (Fig. 1D). For 20 min time (Fig. 1D), the essential oil of *M. viridis* in the volumes of 0.15 and 0.30 µl did not show values of anticoagulant activity statistically different from the values observed for the time of 10 min.

The oil of *M. pulegium* demonstrated to be pro-clotting only in the volume of 0.15 µl, after 10 min of incubation with *B. alternatus* venom (Fig. 1C). Meanwhile, the essential oil from *M. viridis* presented pro-clotting action when incubated with CaCl<sub>2</sub> or citrated plasma and anticoagulant action when previously incubated with *B. alternatus* venom (Fig. 1D).

The effects of essential oils were evaluated on the azocaseinolytic activity by preincubation with different venoms (*B. jararacussu*, *B. moojeni*, *B. alternatus* and *Lachesis muta muta*), before the addition of the protein substrate (Table 1).

In the proteolytic activity on azocasein in liquid medium, essential oil from *M. pulegium*

induced reduction in activity exerted by all the venoms (*B. jararacussu*, *B. moojeni*, *B. alternatus* and *L. muta*), except for 0.6 µl of oil incubated with *B. moojeni* venom (Table 1). The highest inhibitions were obtained on *B. jararacussu* venom with 34.33 % and 39.99 % inhibition for 0.6 and 1.2 µl volume, respectively. The higher volumes (2.4 and 4.8 µl) could not be evaluated in liquid medium, since resulted in changes in spectrophotometric analysis.

*M. viridis* essential oils (0.6 and 1.2 µl) reduced the azocaseinolytic activity induced by *B. jararacussu* venom, in 40.93 % and 57.72 %, respectively. On *B. moojeni* venom, the same volumes were responsible for inhibitions of 74.67 % and 47.4 %, respectively. However, for *B. alternatus* and *L. muta* venoms, activity evaluation in liquid medium resulted in potentiation of substrate breakage, with activity increased between 20.84 % and 54.61 % (Table 1).

In the azocaseinolytic activity in solid medium, 100 % inhibition of the activity induced by *B. jararacussu*, *B. moojeni* and *L. muta* venoms was obtained utilizing the essential oil from *M. pulegium* (2.4 and 4.8 µl). The essential oil from *M. viridis* (2.4 and 4.8 µl) completely inhibited the activity induced by *B. moojeni*, *B. alternatus* and *L. muta* venoms (Table 2). For smaller volume of *M. pulegium* oil the greatest inhibitions were observed on the activity induced by *B. moojeni* (27.27 %) and *B. jararacussu* (20.83 %) (Table 2).

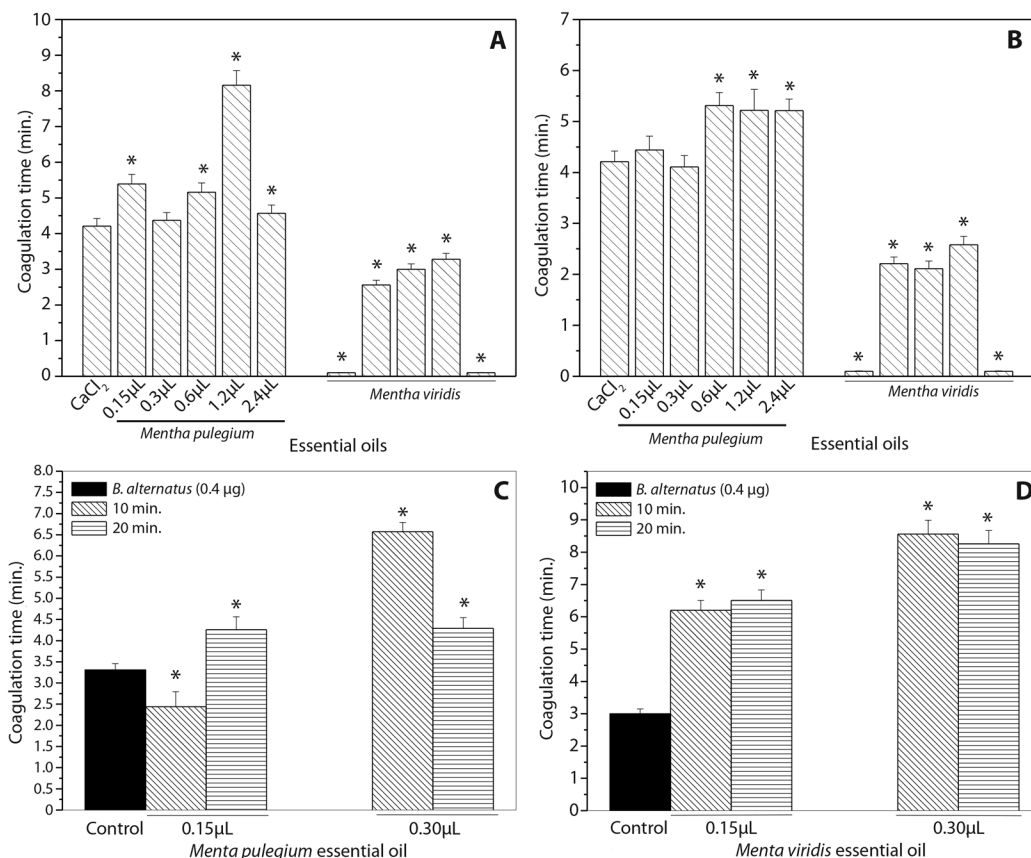

Values obtained to the venoms correspond to 100 % of activity. The data represent mean

TABLE 1  
Effect of essential oils from *Mentha pulegium* and *Mentha viridis* on azocaseinolytic activity, induced by snake venoms, in liquid medium

Essential oil (µl)	Azocaseinolytic activity (%)			
	<i>B. jararacussu</i> (50 µg ml <sup>-1</sup> )	<i>B. moojeni</i> (50 µg ml <sup>-1</sup> )	<i>B. alternatus</i> (100 µg ml <sup>-1</sup> )	<i>L. muta muta</i> (100 µg ml <sup>-1</sup> )
<i>M. pulegium</i>	0.6	65.67 ± 0.04*	103.24 ± 0.13	66.61 ± 0.08*
	1.2	60.01 ± 0.02*	84.35 ± 0.03*	73.07 ± 0.16*
<i>M. viridis</i>	0.6	59.07 ± 0.13*	25.33 ± 0.11*	144.0 ± 0.04*
	1.2	46.28 ± 0.08*	52.60 ± 0.12*	154.61 ± 0.15*

Values obtained to the venoms correspond to 100 % of activity. The data represent mean and standard derivation of analyses done in triplicate. \*Differ statistically from the positive control at 5 % of significance.

**Fig. 1. (D) Previous incubation of different volumes of essential oil from *M. viridis* with *B. alternatus* (10 min. or 20 min.) followed by addition of the citrated human plasma at 37°C and timing. \* Differ from positive control at 5%.

and standard derivation of analyses done in triplicate. \*Differ statistically from the positive control at 5 % of significance.

Essential oils components in the evaluated conditions did not interfere in electrophoretic migration profile in polyacrylamide gel of main classes of proteins (phospholipases A<sub>2</sub> and proteases) present in the venoms (data not shown). However, fibrinogenolytic activity induced by *B. moojeni* venom was completely inhibited by *M. pulegium* oil in two volumes and incubation

times evaluated (Fig. 2A). This essential oil was also effective in protecting fibrinogen molecules against the action of denaturing agents (β-mercaptoethanol and sodium dodecyl sulphate) used during samples preparation for electrophoretic run, since at the end of electrophoresis run it was observed a profile of protein bands with molecular weight greater than the alpha, beta and gamma chains of fibrinogen, probably corresponding to intact fibrinogen molecules (Fig. 2B).

TABLE 2

## DISCUSSION

Chemical composition of *M. pulegium* and *M. viridis* essential oils were previously described by Silva et al., (2015). The majority constituents, identified by gas chromatography coupled to mass spectrometry (GC-MS)

were pulegone (50.01 %), menthol (31.90 %) and menthone (16.56 %) for *M. pulegium* and linalool (40.70 %), carvone (13.52 %) and  $\alpha$ -terpinene (8.56 %) for *M. viridis*.

Data observed in clotting test suggests that there are interactions between constituents of the oils and enzymes, mainly coagulant proteases (fibrinogenolytics), present in the venom evaluated. The fact that the 0.15 µl and 0.3 µl volumes of *M. pulegium* oil have induced similar coagulation times (Fig. 1C) highlights the concomitant action between specific interaction mechanisms and the sequestration of enzymatic ionic cofactors, the latter being widely described for several compounds of secondary metabolism (Havsteen, 1983; Santos & Melo, 2007).

The results obtained in the present work show that the oil volume as well as the time and the incubation procedure are related to different forms of interactions between molecules present in the reaction medium. This suggests that essential oils interact with venom constituents, and with plasma components. They may act to protect blood molecules against the action of toxins or as enzyme inhibitors or enhancers, interacting directly with the toxins.

Miranda et al. (2014) described assays with rhizome and leaves essential oils from *Hedychium coronarium* in which the authors preincubated these oils with *B. moojeni* venoms

before the addition of plasma. The data obtained by these authors corroborate the results found in the present work, whose inhibitory effect on coagulation induced by the venom is evidenced when the oils are submitted to presence of venoms before addition of plasma. It suggests interactions between terpene compounds from essential oils and proteins, mainly thrombin-like, present in venoms, responsible for the coagulant action.

A study revealed that anethole isolated from *Foeniculum vulgare* essential oil, inhibits clot retraction and platelet aggregation to a greater extent than the essential oil from which it is extracted, suggesting that the anticoagulant action present in the essential oil of *Foeniculum vulgare* is due to the presence of anethole (Tognolini et al., 2007).

The most widely used anticoagulant is heparin. However, because it has animal origin, it can induce diseases in mammals such as avian influenza and bovine spongiform encephalopathy (Mendes et al., 2008), reinforcing the need to find new anticoagulants and antithrombotic agents from plants.

*Mentha viridis* and *M. pulegium* essential oils promoted changes in coagulation time of citrated human plasma. Possible interactions of the constituents of the oils with human proteins that participate in blood coagulation cascade must be considered. It was also confirmed the induction between the constituents of the oils and proteases present in the venom. However, the interactions between these different molecules need to be better investigated, since in the proteolysis tests we could observe both potentiating and inhibitory action.

In the snake venoms from *Bothrops* and *Lachesis* genus, the proteolytic enzymes are the main responsible for the clinical manifestations observed in the accidents (Fonseca, 2010). Borges et al. (2001) verified the ability of *Casearia sylvestris* plant extracts in inhibiting proteases present in several *Bothrops* venoms. Anti-ophidian properties of *Pentaclethra macroloba* (Fabaceae) aqueous extract were also evaluated and this extract exhibited total inhibition of hemorrhagic and nucleolytic activities

induced by different venoms (Silva et al., 2005). Natural inhibitors of protease generally act by competing with enzyme substrates binding to active site of enzymes (Costa et al., 2010).

The fibrinogenolytic assay allows evaluating the action of proteases and their inhibitors on the proteolysis of fibrinogen molecules. Proteases present in the venoms from *Bothrops* genus generally induces a proteolytic action on  $\alpha$ -chains of fibrinogen molecules, not being very effective in degrading  $\beta$ -chains and without action on  $\gamma$ -chain (Silva et al., 2012; Torres et al., 2012).

Considering the varied essential oils composition, it is possible to suggest that metal ion chelating molecules, substances with a hydrophobic character capable of modifying the reaction environment fluidity, or even to interact with toxin sites, acted in a peculiar way that justify the results obtained in fibrinogenolytic activity.

The rhizomes and leaves essential oils from *H. coronarium* did not show any proteolytic effect on fibrinogen (Miranda et al., 2014), corroborating with the results obtained in the present study with *M. viridis* and *M. pulegium* essential oils. Miranda et al. (2014) also described that essential oils were unable to inhibit fibrinogenolysis induced by *L. muta muta*, *B. moojeni* and *B. atrox* venoms at the same conditions (preincubation of venoms or fibrinogen for 30 min at 37 °C with oil volumes of 0.6 and 1.2  $\mu$ l).

Therefore, terpenes and phenylpropanoids that make up the complex mixtures defined as essential oils, found in varying amounts and structures, are responsible for several pharmacological and toxic effects (Miranda et al., 2014). Their wide characterization is made necessary so that they can be used in products intended for human consumption in an effective and safe manner.

In conclusion, the present study presented relevant information since it evaluated different venoms, oils with different compositions and volumes, and distinct substrates. Further studies are needed to provide information on the mechanisms of action of essential oils on

venom proteins and on the possible forms of interaction between their constituents and fibrinogen molecules.

This work was supported CNPq, CAPES and FAPEMIG. The authors express their gratitude to Federal University of Lavras for the support structural and logistic to the researchers.

## RESUMEN

**Inhibición por aceites esenciales de *Mentha viridis* y *Mentha pulegium* (Lamiaceae) de la proteólisis, fibrinogenólisis y coagulación causada por venenos de serpientes.** Los venenos de serpientes son ampliamente utilizados como herramientas de laboratorio para estudios de mecanismos fisiológicos, farmacéuticos y toxicológicos. Los venenos son recursos ricos en diferentes clases de proteasas que actúan sobre los factores de la cascada de coagulación, fibrinogenólisis y fibrinólisis, alterando los procesos homeostáticos y las fosfolipasas A<sub>2</sub>, los cuales están involucrados en procesos inflamatorios y de coagulación. Los productos naturales como los aceites esenciales se componen de ingredientes activos de amplia aplicación en las industrias alimentaria, farmacéutica y cosmética. El presente estudio evalúa los aceites esenciales de *Mentha viridis* y *Mentha pulegium* sobre la coagulación, fibrinogenólisis y degradación de azocaseína, inducida por los venenos de *Bothrops* sp. y *Lachesis muta muta*. Los aceites esenciales fueron obtenidos por hidrodestilación y sus componentes principales fueron identificados respectivamente como el linalool (40.70 %), carvona (13.52 %) y  $\alpha$ -terpineno (8.56 %); pulegone (50.01 %), mentol (31.9 %) y mentona (15.56 %). Los aceites esenciales fueron previamente incubados con veneno de *Bothrops alternatus*, durante dos tiempos diferentes, luego se agregó el plasma y fue registrado el tiempo. El aceite de *M. viridis* presentó el más grande potencial anticoagulante. Mientras tanto, el aceite de *M. pulegium* presentó actividad anticoagulante o procoagulante dependiendo de la dosis evaluada. El tiempo

de incubación también influyó en el efecto de los aceites sobre el tiempo de coagulación. En el ensayo azocaseínolítico, el aceite de *M. pulegium* redujo la actividad para todos los venenos evaluados. La inhibición más alta inducida para el veneno de *B. jararacussu* fue de 39.99 %, para *M. viridis* la actividad fue reducida en 57.72 %, mientras que para *B. moojeni*, la mayor inhibición observada fue de 74.67 %. La fibrinogenólisis inducida por el veneno de *B. moojeni* fue totalmente inhibida por ambos aceites en las proporciones evaluadas. Los resultados muestran la presencia de inhibidores de proteasas en los aceites, como las serinas y metaloproteasas (actuando sobre los factores de coagulación o sobre la actividad hemorrágica), como también fosfolipasas A<sub>2</sub> (enzimas involucradas en los procesos de inflamación y coagulación), los cuales son inhibidores de amplia aplicación en áreas médicas y biotecnológicas.

**Palabras clave:** *Bothrops*; *Lachesis*; inhibición de proteasa; aceite esencial; compuestos naturales; propiedades antiofídicas.
