Abstract

This document shows the function of the utilization Rogers-Castro in the modulization of migratory phenomenon in the state of Campeche, Mexico. The important thing in the use of the functions of these characteristics is that they let work in a group of continuous values, although it pass from discret (the group of quinquenal ages) to a group of continuous ages, that avoid the use of alternative methods to do estimations of the migration rate in levels more disaggregated than the group of quinquenal.
