Abstract

Objective: We report a case of strangulated urethral prolapse. Method/Results: A 62 year old female patient presents to the emergency department with complaints of a bleeding vaginal mass, pain referred to the vaginal introitus and dysuria. After being diagnosed with a strangulated urethral prolapse, surgical excision of the prolapsed urethra was performed. Pathologically, vascular proliferation of the angiomatic type with thrombosis and focal recanalization (Masson) and inclusion of rare muscular fibers were recognized. Her postoperative course was uneventful, without any recurrence or abnormal micturition. Conclusion: For the treatment of strangulated urethral prolapse, surgical excision has been widely applied with successful results.
