Abstract

Objective: To report a case, to confirm the therapeutic and early diagnostic importance of the Lateral Radicular Cyst, through microscopic, radiographic and clinical study in order to prevent its developed and bone tissue loss. Case report: This report describes a LRC, between right upper lateral incisor and cuspid in a 28 years old male, who presented a recurrent sinus tract for about six months, after a traumatic event occurred when the patient was 12 years old. Radiographically a radiolucency along the lateral radicular aspect of the mentioned teeth was detected. The teeth affected were endodontically treated. An enucleation of the lesion was done without the application of material bone generator. Conclusions: The endodontic treatment and the removal of the lesion constitutes a satisfactory approach in this type of pathology.
