Abstract
This article reviews, for the first time in the Spanish Language, a recent personality integrative theory, which has generated and continues to generate a great amount of research, not only in Germany but internationally: The Personality Systems Interactions (psi) theory (Kuhl, 2000, 2001). In this paper the main elements of the theory are described: The seven functional personality levels, the four cognitive macrosystems (intention memory, extension memory, intuitive behavioral control, and object recognition system), and the two affective modulation assumptions (positive affect and negative affect) which determine the systems interactions. This theory is not only integrative at a psychological and neurobiological level but it also has an extensive range of applications in clinical psychology, in education, and in organizational psychology.

Keywords
Personality, psi theory, cognitive systems, affective modulation, intentional action, self-development.
