Abstract

Amyloid Light-chain (AL) amyloidosis is a very rare disease. Nutritional and pharmacointeractional aspects are described. Nutrition repletion of malnourished AL patients is an essential strategy for improving treatment efficacy and clinical outcomes. Early diagnosis of AL amiloidosis is difficult to establish due to the fact that signs and symptoms appearing mimic other processes that delay the final correct histological diagnosis. Untreated patients with this disease have a dismal outcome, with a median survival of 10-14 months from diagnosis. The sooner the treatment is established the better the results are. Modern chemotherapeutical agents, based primarily in cyclophosphamide, bortezomid and dexametasone, produce a rapid, deep, and durable response in the majority of patients. Autologous stem cell transplantation remains restricted to selected patients who are generally without advanced cardiac amiloidosis.

(Nutr Hosp. 2015;31:2337-2345)

Key words: AL amiloidosis. Cardiac amiloidosis.

Introduction

Amyloid Light-chain (AL) amiloidosis is a very rare disease. Antibody-producing cells do not function properly and elaborate abnormal protein fibers made of components of antibodies called light chains. These light chains come together to form amiloid deposits in multiple organs which can cause serious damage. Al amiloidosis must always be confirmed histologically. A biopsy specimen should stain positively with Congo red and demonstrate apple-green birefringence under polarized light.

Untreated patients with this disease have a dismal outcome, with a median survival of 10-14 months from diagnosis¹.

Aceptado: 11-II-2015.
Report of one case

Sixty seven year old white Caucasian male. No known allergies. No toxic habits. No familial history of hematological disorders.

Personal history

– Pharmacology treated arterial hypertension, since 8 years before.
– Mild hyperuricemia; no treatment necessary.
– Megacolon. Chronic constipation.
– Surgical operations: tonsillectomy at 30 y.o. Anal fissure 8 years ago. Right carpal tunnel syndrome surgically released in August 30/2013. Mild improvement.
– Present treatment: Dexametasone, aciclovir 800/day, septrim, lanzoprazol, amiodarone, sintrom, furosemid 20 mg/d, spironolactone and zolpiden. Green tea regularly.

Present disease

The patient suffers paresthesias in both hands since January 2013, being diagnosed bilateral carpal tunnel syndrome, with right predominance. Progressive dyspnea during the last six months with dry cough; (diastolic disfunction in EKG) and auricular flutter (Nov 2013). Blood pressure normalized, not needing pharmacological treatment any more. Weight loss of 8Kg, erectile malfunction, and voice changes. No orthostatic hypotension, ortopnea or nocturnal paroxysmal dyspnea. No diarrhea, (Chronic constipation).

Laboratory findings

Blood: creatinine 0.8 mg/dl; normal liver biology (included Alk. Phosphatase); total proteins 63g/L. Serum proteogram with small beta band (13%); albumin 37 g/L. Serum immune fixation: Bence Jones kappa type protein. Free serum light chains: 6800 mg/L, lambda 8,3mg/L; ratio 816. Normal blood coagulation (Quick time 90%) Urine analysis: proteins: 600 mg/24 hours composed of light chains. Urine immune fixation: Bence Jones kappa type. Medullar biopsy: 10-15% plasma cells (aberrant phenotype, kappa restriction). Negative red Congo stain. In FISH study, numerical and structural alteration of ATM gen (11q22) in 12% of analyzed cells (600). Abdominal fat biopsy: no evidence of abdominal amyloid deposits (a second abdominal biopsy performed three weeks later in another institution gave positive results). Rectal biopsy: Inflammatory changes and stromal changes, red Congo positive.

Cardiological study

Troponin I: 0.11 ng/mL (Normal values < 0.08) NT pro BNP: 3570 pg/ml (NV <125). EKG: sinus arrhythmia, low voltage in extremities and poor voltage in precordial area. (Fig 1) Echocardiogram: Left ventricle with slight increase in septal width (13 mm) concentrically with back wall. Ejection Fraction (EF) 60%. Aortic, mitral and tricuspid valves slightly thickened. Slight biauricular dilatation. (Fig. 2).

Cardiac magnetic resonance (MR): concentric myocardial hypertrophy with septal predominance (14 mm). EF: 64%; slight biauricular dilatation; slight pericardial effusion, compatible with cardiac amyloidosis. (Figs. 3-5).

Several auricular fibrillating episodes needing electric cardiac cardio version in two occasions, (catheter ablation radiofrequency of the tricuspid cV isthm) and, finally, bicameral definitive pacemaker implanted (St...

Jude Accent DR MR en DDRr 70-120 lpm con AV 300 ms) in January 7, 2014.

At present the patient is receiving diuretic treatment, antiarrhythmic drug (amiodarone) and anticoagulants.

In Dec 2, 2013 chemotherapy treatment was started, with oral cyclophosphamide, (600 mg, days 1, 8 and 15), subcutaneous Bortezomib (1.3 mg/m², days 1, 4, 8 and 11) and oral dexametasone (reduced doses from 40 to 20 mg, days 1, 4, 8 and 11) in cycles of 21 days (CyBorD). Patient completed six cycles. A significant reduction of circulating free kappa light chains was obtained with this treatment (159 mg/L) having acceptable tolerance.

Clinical exploration

Laboratory findings.
(Hospital Clinic I Provincial, Barcelona, December 17, 2013)

Normal biochemistry, included creatinine and alkaline phosphatase; slight hypertriglicemia. TGP 45 U/L. GGT 164 U/L. Total proteins 62 g/L. Serum proteogram without band. Séric immune fixation: restricted motility component constituted by lgG-kappa, monoclonal nature. Urinary protein: 141 mg/24h. Urine immune fixation: restricted motility component detected, constituted by free kappa light chains; monoclonal nature. Troponin I: 0.081 ng/mL (Reference values <0.050). BNP 326 pg/mL (Ref. values 4-37) Normal hemogram, except for slight neutrofilic leucocitosis. GSR 8 mm/h. Quick time 29% (Treatment with warfarin; factor X: 19U/dL (Reference values 65-135) Negative serology for HIV, HBV and HCV. Normal thyroid profile. IgM dossification: <0.16 g/L (RV 0.36-2.61) IgA: normal, IgG 6.1 g/L (RV 6.8-15.3) Free kappa light chains in serum: 110 mg/L (RV 3.3-19.4), lambda: 2.94 mg/L (RV 5.7-26.3); ratio 37. PAAF of subcutaneous fat: amyloid deposits (Red Congo positive)

Complementary explorations

Echocardiogram: compatible with restrictive miocardioopathy. Moderately hypertrophic left ventriculium (SVtd 14 mm), non dilated; normal global motility. Ejection Fraction (EF) 65%. Diastolic function not evaluable due to bicameral pacemaker rhythm, but

Pacemaker electrodes in right cavities. Slight pericardial effusion.

To summarize, this is a 67 y.o patient with recent diagnosis of light chain kappa amyloidosis, with cardiac (Functional class II, Mayo cardiac stage III) soft tissue (carpal tunnel syndrome) and digestive (Rectum positive Congo red) involvement. Following six cycles with CyBorD the response is excellent, with adequate tolerance. The patient had a “very good partial response”. For this reason further treatment with six cycles with cyclofosamide (650 mg/m² every 4 weeks) and prednisone (30 mg every other day) was conducted until September 2014. Intensification of the treatment with autologous stem cell transplantation (ASCT) and melphalan 200 mg was disregarded. Cardiac staging has been reevaluated by means of biomarkers in serum, echocardiogram and cardiac MR.

Early diagnosis of AL amyloidosis

Early diagnosis of AL amyloidosis is difficult to establish due to the fact that signs and symptoms appearing mimic other processes that delay the final correct histological diagnosis. Every effort must be made towards early detection and diagnosis of AL amyloidosis. There is a direct correlation between early diagnosis and better clinical outcome. (Table I)

Pharmacological treatment

Pharmacological treatment of AL amyloidosis is based primarily in cyclophosphamide, bortezomib and dexamethasone. This combination (CyBorD) produces a rapid, deep, and durable response in the majority of patients with AL, even in the setting of cardiac and multiorgan impairment. Given the time delays of stem cell transplantation, CyBorD may be the fastest and most effective regimen to be reported.

Conventional chemotherapy and intensive treatment with stem cell transplantation

Several studies have shown the efficacy of high-dose dexamethasone-based regimens in inducing haematological responses and prolonging survival. Impressive efficacy, with > 60% haematological response, has been reported with melphalan-dexamethasone regimens with median survival up to 5 years. In experienced centers, intensive treatment and ASCT obtains a similar haematological response rate. ASCT remains restricted to selected patients who are generally without advanced cardiac amyloidosis. In 2007, a French multicentre randomized prospective trial showed that, compared with ASCT, melphalan-dexamethasone had similar efficacy with less toxicity, resulting in increased survival (22.2 months in the ASCT group and 56.9 months in the group with oral melphalan-dexamethasone; P = 0.04). A recent study by Cibeira et al. showed that treatment of selected AL patients with high-dose melphalan and autologous stem cell transplantation resulted in a high organ response rate and long overall survival, even for those patients who did not achieve complete response.

Whereas ASCT is still commonly used in the USA in patients without severe disease, it is no longer used in most European countries, except Germany. Melphalan-dexamethasone has become the first-line treatment in France for the majority of patients.

The proteasome inhibitor bortezomib, a relatively novel chemotherapeutical agent, is offering a much larger percentage of complete and partial remissions. Bortezomib with cyclophosphamide and dexamethasone is showing good tolerance and impressive response rates. This combination, due to its very rapid efficacy, is now the treatment of choice for primary AL amyloidosis.

Warfarin anticoagulation

Unless major contraindications exist, the presence of atrial fibrillation in AL amyloidosis is a very strong indication for warfarin anticoagulation because of a very high rate of thromboembolic events. In severe cardiac amyloidosis, the atrium is infiltrated, and dysfunctional and atrial thrombi may be present even during sinus rhythm. It is therefore prudent to anticoagulate patients with AL amyloidosis even if they are in sinus rhythm if there is a small transmitral A wave seen on transthoracic echocardiography (≤ 20 cm/s).

Malnutrition in AL amyloidosis

Malnutrition is associated with changes in body composition, delayed wound healing, decreased functional capacity, impaired immune function, changes in the different organ systems and intolerance to medical treatment or surgical interventions. Malnutrition leads to sarcopenia. The concept of sarcopenia implies loss of muscle mass and function. It is a condition that accompanies aging, although it not always has clinical consequences. It is produced by many factors: nervous system (loss of alpha motor units in the spinal cord), muscular (loss of muscle quality and mass), humoral
(decrease in anabolic hormones such as testosterone, estrogens, GH and increase of several interleukines), and life style (physical activity). The main clinical consequences of sarcopenia relate with functional independence. Thus, the sarcopenic patient has greater difficulty walking, or does it more slowly, climbing up stairs, or doing basic daily living activities. These difficulties increase the risk for falls and fractures. They also affect bone formation, glucose tolerance, and body temperature regulation. Besides, dependency is a mortality risk factor.

Malnourished patients are at risk of experiencing infectious and cardiorespiratory complications, increased morbidity and mortality and prolongation of hospital stay. Nutritional intervention is essential, including patients with good previous nutritional status, since the worsening of nutritional status due to critical illness will be a determinant factor of poor subsequent outcome.

AL amyloidosis is often diagnosed at an advanced stage, when treatment perspectives are limited or patients are less likely to tolerate chemotherapy. Nutrition status should be systematically evaluated in AL with simple and objective measurements. Malnutrition at diagnosis of AL amyloidosis is a frequent comorbidity and an independent predictor of mortality. The prognostic value of nutrition status becomes evident approximately 4-6 months after diagnosis, when treatment response can be expected. Future research may demonstrate that nutrition repletion of malnourished AL patients is an essential strategy, including those with good previous nutritional status, for improving...

Malnutrition, pharmaconutrition and other considerations in AL amyloidosis, a rare disease with masquerading symptoms...
treatment efficacy and clinical outcomes. In AL amyloidosis, malnutrition at diagnosis is a frequent co morbidity that affects the prognosis independently of hematologic response to treatment and cardiac stage. Nutrition status should be systematically considered in future intervention trials in AL amyloidosis. Nutrition support trials are warranted.

Pharmaconutrition: functional food

It has been demonstrated, or at least suspected in many instances, that specific nutrients do play a role in nutritional metabolic support. Glutamine, argine, ω-3 fatty acids, and RNA have shown beneficial effects postoperatively following abdominal surgery through the beneficial effect of pharmaconutrition in wound healing and in reduction in suture dehiscences. Given the essential action of micronutrients (vitamins, trace elements) in maintaining immune and antioxidant system function, their supply is necessary in any patient susceptible to these deficiencies, even if of subclinical type. In some instances certain micronutrients or antioxidants exert a proven or suggested specific effect and therefore should be recommended11. A food can be regarded as “functional” if it is satisfactorily demonstrated to affect beneficially one or more target functions in the body, beyond adequate nutritional effects, in a way which is relevant to either the state of well-being and health or the reduction of the risk of a disease. The beneficial effects could be either maintenance or promotion of a state of well-being or health and/or a reduction of the risk of a pathologic process or a disease.

Green tea contains an active polyphenol called Epigallocatechin Gallate (EGCG). Consumption of EGCG in patients with cardiac involvement with AL amyloidosis apparently causes a significant decrease in left ventricular wall thickness and mass, as well as an improvement in NYHA functional classification and left ventricular ejection fraction. Green tea might be useful to diminish cardiac amyloid deposits and improve function in AL amyloidosis. The effects of dietary supplement with epigallocatechin gallate (EGCG) are currently in progress. The end point of these studies is to clarify if EGCG causes a significant decrease in left ventricular wall thickness and mass, as well as an improvement in NYHA functional classification and left ventricular ejection fraction.

A Phase II open-label randomized study of dietary supplement with epigallocatechin gallate (EGCG) to improve cardiac dysfunction in patients with AL amyloidosis is being conducted in Pavia, Italy. The

Hematologic (Immunoclinical) Response Criteria

- **Complete response (CR)**
  Serum and urine negative for a monoclonal protein by immunofixation
  Free light chain ratio normal
  Marrow< 5% plasma cells

- **Partial response (PR)**
  Serum M component> 0.5 g/dL, a 50% reduction
  Light chain in the urine with a visible peak and >100 mg/day and 50% reduction
  Free light chain>10 mg/dL (100 mg/L) and 50% reduction

- **Progression From CR**
  Any detectable monoclonal protein or abnormal free light chain ratio (light chain must double)

- **From PR or stable response.**
  50% increase in serum M protein to > 0.5 g/dL or 50% increase in urine M protein to > 200 mg/day;
  A visible peak must be present
  Free light chain increase of 50% to >10 mg/dL (100 mg/L)

- **Stable**
  No CR, no PR, no progression

recruitment period of this study is being conducted at this time. Therefore results will not be available until at least 2016.

Cardiac complications of myocardial amyloid fibril deposition

An update in diagnosis and management of cardiac amyloidosis has been published by Mohty et al. Symptoms are non-specific: dyspnoea due to heart failure, syncope, vertigo due to rhythm or conduction disorders and, rarely, chest pain. This is the reason why diagnosis is delayed (Tables I-IV). Cardiac involvement may have many serious consequences: severe congestive heart failure with initially preserved LVEF and decreased LV compliance due to amyloid deposit, and advanced diastolic dysfunction; decreased LVEF may follow diastolic dysfunction, leading to terminal and fatal heart failure; chronic elevated LV filling pressure leads to left atrial enlargement then to paroxysmal or persistent atrial fibrillation; atrial thrombi are frequent in cardiac amyloidosis, even in patients with sinus rhythm, and can cause systemic embolic events; non-sustained or sustained ventricular arrhythmias are also potential complications of cardiac amyloidosis; conduction disturbances are prevented and treated by pacemaker implant; orthostatic hypotensive episodes are due to autonomic dysfunction and/or neurovegetative involvement or have a hypovolemic cause; severe dysautonomia can cause syncope and hypotensive cardiac treatment (angiotensin-converting enzyme inhibitors) should be avoided in these patients; autonomic dysfunction can be also expressed by the loss of heart variability; indeed, an SDNN < 50 ms on a 24-hour Holter ECG was found to be an independent predictor of short-term mortality in AL patients. Chest pain may occur in rare cases where amyloid deposits affect the microcirculatory circulation, whereas the macrocoronerary vessels are usually free of significant stenosis.

EKG disturbances in AL amyloidosis

Electrocardiograms (ECGs) are abnormal in 90% of cases with cardiac involvement. The largest study that reported ECG findings consisted of 127 patients with AL and biopsy-proven cardiac involvement. The study confirmed that the two most common abnormalities were low voltage QRS complex (defined as all limb leads < 5 mm in height) and a pseudo infarct pattern on the precordial leads which were seen in roughly 50% of the patients included. Right and left bundle branch block are uncommon. Other changes that may occur include conduction abnormalities (such as second and third degree atrioventricular block), more frequently atrial fibrillation and, rarely, ventricular tachycardia. A fragmented QRS (notches and RsR’ pattern in the absence of QRS prolongation) is significantly more frequent in patients with cardiac amyloidosis (Fig. 2).

Cardiac supportive treatment

Apart from specific treatment of the underlying haematological disease, symptomatic treatment and supportive care are necessary in patients with organ failure. Most drugs commonly used for the treatment of congestive heart failure are inefficient or appear to be dangerous in patients with AL amyloidosis. Beta-blockers are deleterious because they decrease heart rate, which is the only mechanism that can maintain cardiac output in this disease; they may also aggravate autonomic dysfunction like angiotensin-converting enzyme inhibitors. Digitalis has been shown to accumulate in cardiac amyloid deposits. For this reason, digitalis is not recommended.

Loop diuretics, given at high dosage in patients with severe fluid retention, are the mainstay of management. Amiodarone should be considered as first-line therapy for arrhythmia. Anticoagulation therapy is mandatory in patients with supraventricular arrhyth-

Malnutrition, pharmaconutrition and other considerations in AL amyloidosis, a rare disease with masquerading symptoms...
Prognosis in AL amyloidosis

Survival depends mainly on the extension and severity of organ involvement, particularly the presence of amyloid heart disease, and on the haematological response to therapy. Prognosis is influenced relatively little by the underlying, usually non-proliferating, monoclonal plasma cells, even though bone marrow plasma cell infiltration higher than 10% has been associated with poorer outcome. Only 15 years ago, survival in AL amyloidosis was poor, with a median overall survival of 18 months. Since then, the disease prognosis has been transformed with the development of new strategies that efficiently suppress secretion of amyloid-forming LCs, giving a median survival of >5 years. Early diagnosis is therefore a critical step to avoid irreversible damage, especially to the heart.

Final considerations and conclusions

AL amyloidosis is a rare disease with equivocal and masquerading symptoms. Delayed diagnosis is a major factor in poor prognosis. Every effort must be made to make the diagnosis earlier. Timely diagnosis is a great concern. Untreated patients with this disease have a dismal outcome, with a median survival of 10-14 months from diagnosis.

Amyloidosis should be ruled out in all patients suffering carpal tunnel syndrome. The societies of Neurology and Neurosurgery should establish this protocol mandatory. Monoclonal protein testing of the serum and urine is readily available and should be performed on all suspected cases. AL amyloidosis is the most common and dangerous form of amyloidosis and definitely should be ruled out. In addition to serum and urine protein electrophoresis and immunofixation, serum free light chain test can increase the sensitivity (especially in monoclonal light chain only cases) by 10%-15%.

AL amyloidosis must be ruled out also in diastolic insufficiency syndrome and in rapidly developing miocardiopathy. A patient with dyspnoea, unexplained fatigue and LV hypertrophy on TTE contrasting with the microvoltage of QRS amplitude should alert the clinician to an infiltrative process rather than a classical sarcomeric hypertrophic or hypertensive cardiomyopathy; in this case it is important to refer the patient to a specialist in internal medicine and/or a haematologist to perform more specific biological and/or genetic testing.

Extracardiac signs, in addition to unexplained LV thickening on echocardiography in the absence of increased voltage on ECG, favour amyloid cardiomyopathy.

The proteasome inhibitor bortezomib, a relatively novel chemotherapeutical agent, is offering a much larger percentage of complete and partial remissions. Bortezomib with cyclophosphamide and dexamethasone is showing good tolerance and impressive response rates. This combination, due to its very rapid efficacy, is now the treatment of choice for primary AL amyloidosis.

Apart from specific treatment of the underlying haematological disease, symptomatic treatment and supportive care are necessary in patients with organ failure.

Unlike other causes of heart failure, supportive treatment is usually very limited and can be dangerous. Despite important developments in chemotherapy for AL, the prognosis of patients with advanced cardiac involvement remains poor. Finally, a variety of novel specific therapies are on the horizon, which can inhibit new amyloid formation and enhance clearance of existing deposits. Patients should be instructed to control water intake, body weight and urine output on a daily basis in order to prevent overloads and subsequent cardiac insufficiency.

Due to the occurrence of severe cardiac complications, ASCT cannot be offered to all diagnosed patients. Aged patients, i.e. 65 years old or more, should be critically evaluated for transplantation. ASCT remains restricted to selected patients who are generally without advanced cardiac amyloidosis.

Beta-blockers and digitalis, commonly used for the treatment of congestive heart failure, are inefficient or appear to be dangerous in patients with AL and must not be used. Amiodarone should be considered as first-line therapy for arrhythmia.

Loop diuretics, given at high dosage in patients with severe fluid retention, are the mainstay of management. Patients should be instructed to control water intake, body weight and urine output on a daily basis in order to prevent overloads and subsequent cardiac insufficiency.

Anticoagulation therapy is mandatory in most AL amyloidosis.

Pacemaker implantation may be indicated in patients who develop symptoms of bradycardia or conduction disorders. A heart transplant should be considered in selected young patients with advanced amyloid cardiomyopathy, free from other co morbidities.
