ABSTRACT

Palmistichus elaeisis Delvare and LaSalle (Hymenoptera: Eulophidae) is a gregarious and polyphagous parasitot mainly of Lepidoptera pupae. The objective of this paper was to study the development of parasitoid on Bombyx mt. (Lepidoptera: Bombycidae) pupae exposed to one, nine, 18, 27, 36, 45 or 54 female P. elaeisis, respectively. The females of the parasitoid remained in contact with pupae for 24 hours in glass tubes (14.0 \times 2.2 cm), packed in climatic chamber regulated at 25 \pm 2°C, 70 \pm 10% relative humidity and photo phase of 12 hours. With the exception of density 1:1 (72.72%), in other densities parasitism was 100%. Adults of P. elaeisis did not emerge from pupae densities of 1:1 and 9:1, but 100.0% of parasitoid emergence was observed at the density of 45:1 and 54.54% at 54. The duration of the life cycle of this parasitoid ranged from 20 to 28 days. P. elaeisis produced 49 to 589 descendary per pupa of B. mori. The sex ratio of P. elaeisis ranged from 0.93 \pm 0.01 to 0.97 \pm 0.01 without differences with 27, 36, 45 and 54 females/host. This parasitoid should be reared with the density of 45 females per pupa of B. mori.

Key words: alternative host, biological control, mass rearing, parasitism rate, parasitoids.

INTRODUCTION

The family Eulophidae comprises 297 genera and 4.472 species worldwide. They are end or ectoparasitoids; idiobionts or koinobionts; solitary or gregarious; primary or secondary parasitoids; specialists or generalists (Noyes 2003, Pereira et al. 2008b). Many eulophid species are studied and used with success in biological control pro-

Palmistichus elaeisis Delvare and LaSall menoptera: Eulophidae) is a gregarious endopar mainly of Lepidoptera pupae. This species was re in Brazil in Eupseudosoma involuta (Sepp) (Letera: Noctuidae) and Euselasia eucerus Hewitson doptera: Riodinidae) (Delvare and LaSalle 1993) lodes sp. (Lepidoptera: Geometridae) (Bittenco

FABRICIO F. PEREIRA et al.

Brazil (Pereira et al. 2008b), being one important natural enemy due to their attack rate (Zanuncio et al. 2009).

The mass rearing represents an important stage of control programs (Parra et al. 2002, Pastori et al. 2008, Pereira et al. 2009), and the nutritional quality, size, age, mechanical resistance and capacity of immunological response of parasitoids should be considered to select alternative hosts (Godfray 1994). *P. elaeisis* showed a good reproductive performance (adequate parasitism, emergence, progeny per pupa, and size of the body, besides longevity of males and females and sex ratio) when reared on pupae of the alternative host *Tenebrio molitor* Linnaeus (Coleoptera: Tenebrionidae). In addition, the low cost to rear this alternative host indicates that it could be easily used to mass rear the parasitoid *P. elaeisis* for biological control programs (Zanuncio et al. 2008).

The density of parasitoids per host affects the parasitoid offspring (Thomazini and Berti Filho 2000, Matos Neto et al. 2004), the sex ratio (Choi et al. 2001), the parasitism capacity (Sampaio et al. 2001), the duration of the life cycle, the size of the body, and the longevity of the imagines (Silva-Torres and Matthews 2003). To minimize the cost and labor and to maximize the production of parasitoids in mass rearing programs, it is, therefore, necessary to study the density of the parasitoids in relation to the host (Sagarra et al. 2000a).

Palmistichus elaeisis are reared on pupae of Diatraea saccharalis (Fabricius) (Lepidoptera: Pyralidae), Anticarsia gemmatalis Hubner, Heliothis virescens (Fabricius), Spodoptera frugiperda (Smith) (Lepidoptera: Noctuidae) and T. arnobia (Bittencourt and Berti Filho 1999, 2004, Pereira et al. 2008b), but the number of females of P. elaeisis per pupae is not known. This is important because P. elaeisis is a gregarious parasitoid, which makes necessary to define the ideal density of its females per pupa of the host to increase the production of descendants with similar quality to native ones.

Bombyx mori L. (Lepidoptera: Bombycidae) has been reared with low cost, and its pupa has high nutritional quality (Greiss et al. 2003, Wang-Dun et al. 2004).

MATERIALS AND METHODS

The experiment was developed in the Laboratory of Biological Control of the Department of Animal Biology of the "Universidade Federal de Viçosa" (UFV) at Viçosa, Minas Gerais State, Brazil, as:

REARING B. mori

The Sericiculture Laboratory of the Department of Animal Biology (UFV) provided first instar caterpillars of *B. mori* that were placed in plastic trays (39.3 \times 59.5 \times 7.0 cm) with *Morus alba* L leaves, which were changed daily. The pupae obtained of *B. mori* were transferred to plastic trays (28.3 \times 36.0 \times 7.0 cm) and placed in an acclimatized chamber at 25 \pm 2°C, 70 \pm 10% relative humidity (RH) and a photo phase of 12 hours.

REARING THE PARASITOID

Adults of *P. elaeisis* were kept in glass tubes (14.0×2.2 cm) with honey droplets as food. The tubes were closed with a cotton plug. Forty-eight to 72 hours old pupae of *B. mori* were removed from their cocoons and exposed to the parasitoid females during 24 hours in the acclimatized chamber.

Effect of the Parasitoid Density on the Biology of P, elaeisis

Pupae of *B. mori* (weight $1.06 \pm 0.01g$) and females of *P. elaeisis*, both with 72 hours old, at the densities of 1:1, 9:1, 18:1, 27:1, 36:1, 45:1 and 54:1 (parasitoid: host), were reared in an acclimatized chamber at $25 \pm 2^{\circ}$ C, $70 \pm 10\%$ relative humidity (RH) and a photo phase of 12 hours. Each pupa was exposed to the parasitism by females of *P. elaeisis* into glass tubes (14.0 cm \times 2.2 cm) for 24 hours under the conditions user. These females were removed from the tubes at the end of this period.

The parameters evaluated were: the duration of the life cycle (egg-adult), the percentage of parasitism [without the natural mortality of the host (Abbott 1925)], the percentage of emergence of the progeny, the number and size of parasitoids that emerged per pupa, the number of immature that did not complete their development, the sex ratio (which was calculated by the equation SR = number of females/number of males and females). The

The treatments were represented by the densities of one, nine, 18, 27, 36, 45 and 54 P. elaeisis females per pupa of B. mori in 12 replications in an entirely casualized design. The data of the duration of the life cycle, the number of parasitoids that emerged per pupa and the percentage of dead immature were submitted to a variance analysis. The regression analysis was done with the computer program SigmaPlot 8.0 when the data presented differences at 5% probability. The percentages of parasitism and emergency of P. elaeisis were submitted to the analysis of general linear models (GLM) with binomial distribution (P<0.05) with the computer program R Statistical System (Ihaka and Gentleman 1996). This analysis was carried through with the original data that are not-parametric, but these had been expressed in percentage to facilitate the visualization. The data of the sex ratio and those of the size of the body of females and males of P. elaeisis were submitted to a variance analysis and to the test of Scott-Knott with the computer program SAEG 9.0 when they were different at 5% probability.

RESULTS

The density of females of P. elaeisis affected their percentage of parasitism and the number of specimens of this parasitoid that emerged per pupa of B. mori. A total of 72.72% of pupae of this host were parasitized at the density of 1:1, while this number was 100.00% for other densities (P = 0.0312) (Fig. 1). No specimens of P. elaeisis emerged from pupae of P. mori at the densities of 1:1 and 9:1, but those of 45:1 and 54:1 had 100.00% and 54.54% of pupae with parasitoid emergence, respectively (P = 0.0055) (Fig. 1).

The duration of the life cycle (egg-adult) (P = 0.0001; $df_{error} = 30$) decreased as the density of *P. elaeisis* increased with values from 20 to 28 days (Fig. 2). The density of this parasitoid per pupa of *B. mori* (F = 4.7025; P = 0.0170; $df_{error} = 31$) affected the progeny that was produced. The number of offspring per pupa of *B. mori* ranged from 49 to 589, but no offspring was produced at the densities 1:1 and 9:1 (Fig. 3). The progeny per female of *P. elaeisis* per pupa of *B. mori* was similar, with 18, 27, 36, 45 e 54 females of this parasitoid per pupa

8.8088; P = 0.0006; df_{error} = 49) (Fig. 5) with numbers (6.83 \pm 1.72) at the density of 45:1. Tratio of *P. elaeisis* ranged from 0.93 \pm 0.01 to 0.01, with similar values at all densities (F = 2. 0.06962) (Table I).

The length of the body of adult *P. elaeisis* width of the head capsule differed among the dof females of this parasitoid. The length of the of females and males of *P. elaeisis* ranged from 0.04 to 1.89 ± 0.02 mm (F = 3.707; P = 0.0090 from 1.34 ± 0.01 to 1.54 mm ± 0.03 (F = 5.44 ± 0.00091), respectively (Table I). The width of the capsule of females and males of *P. elaeisis* ranged 0.47 ± 0.01 to 0.50 ± 0.01 mm (F = 3.355; P = 0.01 ± 0.01 mm (F = 0.00497), with the densities of 18 and 54 to of this parasitoid per pupae of *B. mori* (Table I).

DISCUSSION

The percentage of parasitism and emergence of I sis per pupa of B. mori showed that the optimal of females of this parasitoid per pupae of this host be 45 for its mass rearing. The progeny of P. elae be affected by the number of females of P. elae pupae of B. mori. This indicates that inadequat bers of females of this parasitoid can reduce the of eggs laid per host and the amount of toxins inje the pupa by the female wasps. The toxins are ne to reduce the immunological response from the defense mechanism used by the pupa to encapsula and/or larvae of the parasitoid (Schmid-Hempel So, eggs of P. elaeisis may be encapsuled and of pupal hemocyts when the female density of this sitoid per host is low to suppress the immune re Nevertheless, high doses of toxins injected by m male P. elaeisis per pupa may kill the host bef complete development of the immature parasitoid (Strand and Pech 1995).

The reproductive parameters of *P. elaeisis* of from those of *Trichospilus diatraeae* Cherian an gabandhu (Hymenoptera: Eulophidae) and from of *D. saccharalis*. *A. gemmatalis*. *H. virescens*

18:1	12	$0.95 \pm 0.01a$	$1.81 \pm 0.05a$	$1.54 \pm 0.03a$	$0.48 \pm 0.02b$	$0.44 \pm 0.01a$
27:1	12	$0.95 \pm 0.01a$	$1.83 \pm 0.03a$	$1.49 \pm 0.05a$	$0.49 \pm 0.01b$	$0.41 \pm 0.02a$
36:1	12	$0.93 \pm 0.02a$	$1.83 \pm 0.06a$	$1.49 \pm 0.03a$	$0.49 \pm 0.01b$	$0.42 \pm 0.01a$
45:1	12	$0.93 \pm 0.01a$	$1.89 \pm 0.02a$	$1.46 \pm 0.03a$	$0.50 \pm 0.01a$	$0.44 \pm 0.01a$
54:1	12	$0.97 \pm 0.01a$	1.67 ± 0.04 b	$1.34 \pm 0.01b$	$0.47 \pm 0.01b$	$0.38 \pm 0.01b$

N = number of parasitoids measured. / Means followed by the small letter in the same column do not differ among densities by the Scott-Knott test ($P \le 0.05$). / — Without emergence of *Palmistichus elaeisis*.

obtained with several females of this parasitoid per pupa (Paron and Berti Filho 2000). On the other hand, the percentage of parasitism and the emergence of *Aphidius*

does not present any nutritional or physiological barriers for the development of *A. colemani* (Sampaio et al. 2001). *B. mori* might have an efficient defense mech-

The absence of offsprings of P. elaeisis at the density 1:1 can be due to the encapsulation of its eggs by the immune defense of the pupa of B. mori. This mechanism and the melanization constitute the main defense of insects against strange materials in their bodies (Schmid-Hempel 2005). On the other hand, parasitoids can avoid the encapsulation by injecting particles that are similar to virus, polidnaviroses or poisons into the host to interfere with its immunological recognition (Strand and Pech 1995, Schmidt et al. 2001, Nakamatsu and Tanaka 2003), as well as the depletion of the immune system that has high energy cost, is finite and can be neutralized by toxins from parasitoids (Schmid-Hempel 2005). These hypotheses may explain the high number of P. elaeisis per pupa of B. mori at the in density of 54:1, suggesting that this amount of female parasitoids is sufficient to neutralize the immune response of this host. The decrease on parasitoid progeny with the density 54:1 parasitoid:host suggests the occurrence of superparasitism.

The shorter life cycle duration of *P. elaeisis* in the densities 36:1; 45:1 and 54:1, indicates that the competition for nutrients reduced the development of these immature parasitoids. This agrees with reports for different densities of *Melittobia digitata* Dahms (Hymenoptera: Eulophidae) per pupa of *Neobellieria bullata* Parker (Diptera: Sarcophagidae) (Silva-Torres and Mathews 2003). The duration of the immature stages of *P. elaeisis* with *A. gemmatalis*, *D. saccharalis*, *S. frugiperda*, *T. arnobia* and *H. virescens* was 18.9, 19.5, 19.7, 20.2 and 22.0 days, respectively. These results demonstrate that the host species also affects the development period of this parasitoid (Bittencourt and Berti Filho 2004).

The similar number of progeny per female of *P. elaeisis* in the densities 18:1, 27:1, 36:1, 45:1 and 54:1, parasitoid:host shows that this natural enemy control the number of eggs per ovipositon and recognizes non parasitized, parasitized or super-parasitized hosts. However, the competition, size and age of the parasitoid, besides the number of eggs encapsulated by the host, can also affect the number of offsprings (Godfray 1994, Sagarra

meron (Gonzáles et al. 2004), *Melittobia austral* rault and *M. digitata* (Silva-Torres and Matthews suggesting that a high sex ratio is characteristic lophidae.

The smaller size of emerging adult *P. elaeist* density 54:1 indicates the occurrence of compet nutrients during the larva stage of this parasitoic is important because the size of the body is po correlated with the longevity, fecundity, reproduc riod, emergence of the progeny and sex ratio, wh indicators of quality and efficiency of the para Large females and males of Anagyrus kamali (Hymenoptera: Encyrtidae) lived longer (35.4 : 29.16 ± 6.5 days) than small ones (27.9 ± 9.6; 5.7 days), respectively, but females of A. kamali with males large rather or small, no preference. ever, the fecundity of A. kamali was positively con with the size of the females, with values of 37 \pm 2 for small females, and 96 \pm 43 for large female parasitism capacity, daily oviposition rate and th ber of offsprings per female of A. kamali showed values for large specimens. This suggests the ne of using larger specimens and to monitor mass facilities in order to maximize the production of sitoids (Sagarra et al. 2001).

Palmistichus elaeisis parasitized B. mori p the density of 1:1, 9:1, 18:1, 27:1, 36:1, 45:1 at (parasitoid: host), but densities below or above 4 sitoids per pupa are inadequate for producing low of descendants, besides favoring the auto-immur of B. mori pupae. This parasitoid should be rear the density of 45 females per pupa of B. mori in tory and economic studies (Monteiro et al. 2006) field (Pratissoli et al. 2005a, b) it must be condube applied in biological control programs.

RESUMO

Palmistichus elaeisis Delvare e LaSalle (Hymenoptera: Eulophidae) é um parasitóide polífago, que inviabiliza, principalmente, pupas de lepidópteros. O objetivo desse trabalho foi estudar o desenvolvimento do parasitóide em pupas de Bombyx mori L. (Lepidoptera: Bombycidae) expostas a uma, nove, 18, 27, 36, 45 ou 54 fêmeas de P. elaeisis, respectivamente. As fêmeas do parasitóide permaneceram em contato com as pupas por 24 horas em tubos de vidro (14,0 × 2,2 cm), acondicionadas em câmara climatizada regulada a 25 ± 2°C, 70 ± 10% de UR e fotofase de 12 horas. Com exceção da densidade 1:1 (72,72%), nas demais densidades o parasitismo foi 100%. Adultos de P. elaeisis não emergiram nas densidades de 1:1 e 9:1, mas observou-se 100% de emergência do parasitóide na densidade 45:1 e 54,54% em 54:1. A duração do ciclo de vida desse parasitóide variou de 20 a 28 dias. P. elaeisis produziu de 49 a 589 descendentes por pupa de B. mori. A razão sexual de P. elaeisis variou de 0.93 ± 0.01 a 0.97 ± 0.01 sem diferenças nas densidades de 18, 27, 36, 45 e 54 fêmeas/hospedeiro. Esse parasitóide deve ser criado na densidade de 45 fêmeas por pupa de B. mori.

Palavras-chave: hospedeiro alternativo, controle biológico, criação massal, taxas de parasitismo, parasitóides.
