Received July 11, 2013; accepted February 5, 2014

Abstract The objective of this research study was to assess pharmacological, somatic and/or psychological treatments in adults with a diagnosis of major depressive disorder who have not responded to at least one course of antidepressant medication. We conducted a systematic review to identify systematic scientific reviews and meta-analyses on treatment-resistant depression (TRD) published until February 2012. Of the sixty studies selected, sixteen met the inclusion criteria and were therefore included in the review. We considered eight main themes, including the definition of TRD, long-term results, and different treatment strategies, including so-called somatic therapies. Based on the review, the definition of TRD should be standardized in order to achieve a shared conceptualization of this disorder. This would allow a better understanding among clinicians and researchers in the field, promoting a homogeneous research methodology and thus leading to more reliable and comparable results. This essential conceptual clarification would also have a positive impact on patients with TRD, their families, and social and health systems.

Resumen El objetivo de esta investigación es analizar la literatura científica sobre los tratamientos farmacológicos, somáticos y/o psicológicos en adultos con diagnóstico de un trastorno depresivo mayor que no han respondido al menos a un tratamiento con antidepresivos. Se llevó a cabo una revisión sistemática sin limitación temporal para identificar las revisiones sistemáticas y meta-análisis publicados hasta febrero de 2012 en DRT. Sesenta estudios fueron seleccionados de entre los cuales quedaron incluidos diecisésis al cumplir con los criterios de inclusión. Se sintetizan ocho temas principales entre los que cabe destacar la definición, resultados a...
Depression is one of the most common mental disorders in current Western societies. At present, it continues to grow in numbers and is one of the main causes of disability around the world, particularly in high-income regions (e.g., Davidson, 2010; McKenna, Michaud, Murray, & Marks, 2005; World Health Organization [WHO], 2005). To deal with this relevant health and social problem, there are several efficient interventions such as use of antidepressant drugs (ADs; Geddes et al., 2003; Perestelo-Pérez et al., 2010) and psychological treatments, particularly those derived from a cognitive-behavioural approach (Aguilera, Garza, & Muñoz, 2010; Kaltenhailer et al., 2006; Merry, McDowell, Hetrick, Bir, & Muller, 2004).

Despite these efficient treatment tools, up to 50% of individuals with depression do not show significant clinical recovery. Hence, a large proportion of the burden caused by depression has been attributed to ‘treatment-resistant depression’ (TRD; Álvarez et al., 2008; Eby & Eby, 2010; Jenkins & Goldner, 2012).

TRD is most likely to occur with comorbid physical and mental disorders as well as marked and protracted functional impairment. It is highly recurrent, with as many as 80% of patients who require multiple treatments relapsing within a year of remission and a probability of recovery of about 40% within 10 years. Thus, TRD is the subject of a considerable amount of research aimed at reducing the substantial burden and high healthcare costs it originates (Fekadu et al., 2009).

As happens with other depressive disorders, there are different treatment approaches to TRD. New protocols and treatment resources have been developed to treat this disorder. A few examples are combination or augmentation strategies (Mahmoud et al., 2007; Shelton, Osuntokun, Heinloth, & Corya, 2010; Vigo & Baldessarini, 2009) and repetitive transcranial magnetic stimulation (rTMS; Padberg & George 2009; Schlaepfer, George, & Mayberg, 2009). Despite these efforts, the situation remains unclear and no specific protocol is recommended to treat TRD (National Institute for Health and Clinical Excellence [NICE], 2009).

The aim of the present systematic review (SR) was to identify published systematic reviews (SRs) and meta-analyses to assess pharmacological, somatic and/or psychological treatments in adults with a diagnosis of major depressive disorder who have not responded to at least one course of antidepressant medication. We conducted this SR based on the recommendations of Fernández-Ríos and Buela-Casal (2009) and Perestelo-Pérez (2013).

Method

Search strategy

We systematically reviewed materials published until September 2012, consulting the following databases: Medline, Medline In-Process, Old Medline, Embase, Cochrane, Cinahl, and PsycInfo. We developed a search strategy for each electronic database using the combination of the following Medical Subject Heading (MeSH) and free-text terms: pharmacology, antidepressant, psychology, psychotherapy, psychoeducation, combination, depression, depressive disorders, systematic, review, and the names of individual antidepressants and individual psychotherapies. An experienced information specialist developed, tested, and refined the search strategies with input from the authors (full details are available on request).

To complete the information sources, we scrutinized reference lists of selected review papers manually for further relevant articles and reports. We increased the number of articles available by conducting additional searches on the Internet and in book chapters and contacting relevant authors in the field.

Inclusion and exclusion criteria

The scientific articles included in the SR were systematic reviews (SRs) and meta-analyses on TRD assessing the efficacy of pharmacological, somatic and/or psychological treatments for TRD with the aim of directly or indirectly improving patients’ depressive state. No language restrictions were applied. Intra-group comparison studies, narrative reviews, case studies, and expert consensus studies were excluded.

Studies included were those in which participants were adults up to 65 years old with a depressive disorder according to the diagnostic criteria of the International Statistical Classification of Diseases and Related Health Problems (CIE-10; World Health Organization, 1992) or the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV; American Psychiatric Association [APA], 2000); participants had to suffer from TRD, understood as depression that had not responded to two adequate antidepressant treatments, or be recruited according to their scores in a validated questionnaire measuring depression such as the Montgomery-Asberg Depression Rating Scale (MADRS, Montgomery & Asberg, 1979) or the HAMD rating scale (Hamilton, 1960).

Studies excluded were those in which participants had any of the following: an episode or disorder attributable to
the consumption of psychoactive substances or to a medical illness, a history of episodes of hypomania, mania, or a combination of both, a cyclothymic disorder, a new major Depressive episode or one superimposed to or better explained by another mental disorder, any other organic mental disorders, or pregnancy-related depression. Studies involving infant, youth, or geriatric patients were also excluded.

**Study selection process**

The study selection process was carried out separately by two reviewers to reduce the possibility of rejecting relevant articles. Reviewers used the following blinded and structured hierarchical strategy: first, reading titles and abstracts; second, reading the articles selected in the first phase in full; third, selecting articles fulfilling the specific inclusion criteria. If any discrepancies arose, a third reviewer verified the selection criteria and a consensus was reached.

**Data extraction**

Data were extracted independently by the same researchers who selected the studies, who received previous training for this purpose. Any disagreements were solved by consensus with the help of a third reviewer. The following information was extracted from each of the SRs considered: databases consulted, use of a manual search or not, time period reviewed, study inclusion criteria, number of studies and sample size, main objective of the SR, and main conclusions of the SR.

**Quality assessment**

Each article was critically assessed according to its methodological quality. To select articles of scientific value meeting the pre-specified inclusion and exclusion criteria and reduce bias, SRs had to exceed at least 50% of the maximum score of the scale (Oxman ≥ 5). Two reviewers independently assessed included studies using the Oxman Scale (Oxman, Cook, & Guyatt, 1994). In this scale, scores range from 0 to 10 points; higher scores indicate a better quality. The scale assesses five areas: i) definition of the subject of study of the review (2 points); ii) selection of review articles (2 points); iii) importance and relevance of articles reviewed (2 points); iv) assessment of the quality of studies reviewed (2 points); and v) combined results of studies reviewed (2 points).

Any doubts or disagreements between both reviewers were resolved by verifying the protocol criteria and subsequently reaching consensus.

**Results**

**Identified studies**

Using the search strategy described above, we identified a total of 21,446 references. After eliminating duplicates, we retained 13,367 references. Of these references found as of February 2012, 103 were selected by title and abstract. The search and selection process used to identify references is shown in Figure 1.

Given the large number of SRs identified, we decided to limit the review period to cover SRs published since the year 2000, assuming that they would include relevant information from previous years.

**Included and excluded studies**

Of the 60 SRs selected and read in full, the following 16 were included: Barowsky & Schwartz, 2006; Bauer, Tharmanathan, Volz, Moeller, & Freemantle, 2009; Blier & Turecki, 2007; Bschor & Baethge, 2010; Bschor & Bauer, 2006; Daban, Martínez-Aran, Cruz, & Vieta, 2008;...
Methodological quality

Table 1 shows the methodological quality scores of the systematic reviews included according to the Oxman Scale (Oxman, Cook, & Guyatt, 1994).

Characteristics of included studies

Based on the data extraction sheet, we developed Table 2, identifying the main characteristics of the studies, and Table 3, showing the main objective of the systematic reviews included.

Of the 16 SRs included, 13 understood TRD as failure to respond to an antidepressant treatment, one included a partial response to such treatment (Lam et al., 2008) and 6 understood TRD as failure to respond to one or more ADs (Berlim & Turecki, 2007; Bschor & Bauer, 2006; Fekadu et al., 2006, Lam et al., 2002; McPherson et al., 2005; Thomas et al., 2010). Two SRs (Barowsky & Schwartz, 2006; Sarnecki & Temel, 2011) considered Thase and Rush stages (1997) and one SR dealt with TRD staging methods. Table 2 identifies the characteristics of the studies and Table 3 shows the main objective of the SRs included.

The main findings obtained for each SR are shown in Table 4, clustered into eight different themes.

Definition of treatment-resistant depression and staging methods

Overall, results of randomized controlled trials (RCTs) differed in most of the conceptual and methodological issues related to TRD. Among five staging methods found in the literature, the Thase and Rush method was the most widely used.

Long-term results

Although TRD is associated with worse clinical course and clinical and social consequences, its long-term evolution is based on a heterogeneous group of studies of limited methodological quality.

Venlafaxine

Studies provide evidence of the clinical efficacy of this drug in achieving therapeutic response and remission of symptoms. Venlafaxine appears to be more effective than selective serotonin reuptake inhibitors (SSRIs) and at least as effective as tricyclic ADs.

Switching ADs

There is a discrepancy between published evidence and the decision to switch ADs frequently in clinical practice.

Combining ADs

Combining ADs with different mechanisms of action is a strategy that seems effective. In fact, some success has
been observed with combinations of bupropion plus an SSRI, reboxetine plus an SSRI, venlafaxine plus mirtazapine, and a monoaminoxidase inhibitor plus a tricyclic AD.

**Augmenting antidepressant drugs**

Adding lithium is recommended as a treatment strategy for patients who do not respond adequately to standard treatment with ADs in international guidelines and reviews. However, there is little evidence of the use of other compounds such as lamotrigine.

**Psychological treatments**

Although such treatments are commonly used and often recommended after medication has failed, there is little evidence of their effectiveness.

**Somatic treatments**

Overall, specific parameters of stimulation and side effects are yet to be defined for rTMS and vagus nerve stimulation, the most beneficial deep brain stimulation techniques.

Discussion and conclusions

There are currently many treatment options available once an AD trial has failed (Ruelaz, 2006), such as switching to another AD (Barowsky & Schwartz, 2006; Bschor & Bauer, 2006), combining two ADs of the same or a different class (Dodd et al., 2005; Lam et al., 2002), or augmenting the AD with other pharmacological substances (Gabriel, 2006; Nierenberg et al., 2003; Rocha & Hara, 2003). However, the present SR revealed that the literature available to date does not show consistent results for any of these strategies. We found a discrepancy between published evidence and the frequent decision to switch, combine, or augment antidepressants in clinical practice.

With regard to somatic treatments, only a moderate percentage of patients were found to gain relief with deep brain stimulation techniques, but results should not be generalized as sample sizes are small and a robust research methodology is needed (Kennedy & Giacobbe, 2007). Repetitive transcranial magnetic stimulation (rTMS) appears to provide significant benefits in short-term treatment studies. Yet, the relatively low response and remission rates, short durations of treatment, and relative lack of systematic follow-up studies suggest that further studies are needed before rTMS can be considered as a first-line monotherapy treatment for TRD (Bretlau et al., 2010; Triggs et al., 2010). Vagus nerve stimulation seems to be an interesting new approach to treat TRD, but results are reported mainly in open studies. Therefore, further clinical trials are needed to confirm its efficacy in major depression. Overall, it has not been possible to determine the most beneficial stimulation areas, parameters, and side effects for these three somatic treatments yet.

<td>There is little evidence to guide the use of lamotrigine for depression that has not responded to a course of antidepressants</td>
</tr>
<tr>
<td>Trivedi et al. (2011)</td>
<td>There is a pressing need to examine psychotherapy as a second step treatment in patients who have not responded to initial antidepressants treatment. This may be addressed in two ways: 1) re-analysis of existing data from trials in which patients with treatment resistant depression are recruited, or 2) conducting studies designed to examine this question. As a field, it is important to develop a standardized, operational definition of treatment resistant depression to facilitate comparisons across studies</td>
</tr>
</tbody>
</table>

Note. TRD = Treatment-Resistant Depression; VNS = Vagus Nerve Stimulation; SSRI = Selective Serotonine Reuptake Inhibitor; MAOI = Monoamine Oxidase Inhibitors; MSM = Maudsley Staging Method; TCA = Tricyclic Antidepressants; VNS =: Vagus Nerve Stimulation; rTMS = Transcranial Magnetic Stimulation; RCTs = Randomized Control Trials.
Data about psychological treatments for depression show that they are commonly delivered and recommended following the failure of medication, but the scarce evidence of their effectiveness in these situations is a significant problem (Anderson, Nutt, & Deakin, 2000; Parker, Blanch, & Crawford, 2010). There is a need for studies with a strong controlled design exploring the effectiveness of psychological treatments for patients with TRD and assessing psychotherapy as a second step treatment in patients not responding to initial treatment with antidepressants. It is also important to develop a standardized, operational definition of TRD to facilitate comparisons across studies (McPherson et al., 2005).

Although it was not the main aim of this research, this systematic review revealed, in line with many research studies (e.g., Bschor, J., & Baethge, C. (2010). No evidence for switching the antidepressant: systematic review and meta-analysis of RCTs of a common therapeutic strategy. Acta Psychiatrica Scandinavica, 121, 174-179.), a considerable heterogeneity regarding most conceptual and methodological issues involved in the ascertainment of TRD in the published literature. More specifically, there are major differences in the number and type of previous failed trials required to make a diagnosis of TRD, the definition of treatment adequacy (dose, titration, and duration) and treatment response, and the assessment of primary and comorbid diagnoses. As regards the five staging methods found by our SR in the literature, the Thase and Rush method (1997) and the Maudsley Staging Method (Fekadu et al., 2009) were those most widely used. However, it is necessary to further explore the reliability and predictive utility of TRD staging models and additional disease characteristics. In this regard, the NICE (2009) proposes understanding TRD from a dimensional perspective for patients who show an inadequate response to treatment. This approach starts with the least intrusive intervention and patients who do not show any response are offered a sequenced structured intervention in several consecutive steps. It should be noted that patients who show a poor response to treatment are also considered in this new conceptualization.

It is important to note that conclusions are limited to the information and methodological quality of the available scientific evidence included in this SR. In addition, the authors consider that the articles published omit information of particular interest in the case of TRD that might be relevant to the interpretation of results (e.g., comorbidity with other disorders or physical or mental illness). In this regard, some of the first articles selected were excluded because they did not include a definition of TRD. In this research, TRD was understood as failure to respond to one or more AD treatments. Therefore, conclusions are to be reached only within this context.
