Abstract
In this paper my aim is to describe the intermediate hypothesis operationalism for the construction of the diagnosis instrument, in this case a questionnaire, that is part of an investigation. Variables are correlated, and a typo is build of the disorders in the sleep and the dreams in patients with organic pathology. Also I studied some clinic parameters related to the psychotherapeutic diagnosis in the treatment of the organic diseases taking into account a neurophysiologic view from the articulation is related. The main purpose of this work is to expose the intermediate hypothesis in order to support the questions framed in the instrument of data collection, this is to say, the questionnaire created for the investigation that explores the exiting links between the different variables: a) function of sleep, b) function of dream, c) oncological pathology, and determine the relation between them. The questionnaire constructed for this investigation has the intention to explore the sleep and dream activities in oncological patients as an expression of the psychic life in general. The oneiric activity can offer clues of other activities of a patient psychology. I am going to refer to two of them, the category “sleep disorder”(SD) and the category “dream disorder” (DD).

Keywords
Diagnosis instrument, operationalism, intermediate hypothesis, function of sleep, function of dream, oncological pathology.
