ABSTRACT. Three new Cyrtochilum species from Peru that are endangered by habitat destruction, are here described, illustrated and compared with similar species.

KEY WORDS: Cyrtochilum, endangered species, Orchidaceae, Oncidiinae, new species, Peru, taxonomy

The genus Cyrtochilum Kunth has gone through quite a taxonomic turmoil during its two centuries long history. The trouble has mainly been caused by difficulties in defining the genus based on floral morphology alone, and to separate it from genera Odontoglossum Kunth (considered as Oncidium by some) and Oncidium Sw. Other species have been placed in various smaller genera, such as Buesiella C.Schweinf., Neodryas Rchb.f., and Rusbyella Rolfe. Thanks to molecular work with DNA sequencing (Williams et al. 2001a, 2001b) we now know a lot more about how these plants are related to each other, although the controversy of how to treat them taxonomically probably will remain for some time yet. The three large flowered species described in this paper, however, are most certainly considered as “typical” cyrtochilums by most people, so little controversy should arise from their descriptions.

TAXONOMIC TREATMENT

Cyrtochilum deburghgaeveanum Dalström & S.Ruíz, sp. nov.

TYPE: Peru, Amazonas, Jumbilla, Florida, Gualulo, alt. ca 2200 m, collected by S. Ruiz and G. Deburghgraeve, Nov. 2010; S. Dalström 3498 (holotype, USM). Fig. 1.

Cyrtochilo cordato (Lindl.) Kraenzl. similis, sed lobulis lateralibus et callo labelli recedit.

Epiphytic herb. Pseudobulbs caespitose or slightly creeping on a bracteate rhizome, oblong ovoid, ca. 10 × 5 cm, distantly bifoliolate (terminal leaf ca. 2 cm above lower leaf), surrounded basally by 7-8 distichous sheaths, the uppermost foliaceous. Leaves subpetiolate, conduplicate, narrowly elliptic to slightly obovate, narrowly acute to slightly obovate, narrowly acute to broadly acuminate, 30-45 × 1.5-2.5 cm. Inflorescence axillary from the uppermost sheaths, erect, then wiry and flexuous, to ca. 160 cm long panicle, with widely spaced 3-5 flowered side branches. Bracts appressed, involute and cucullate, 10-15 mm long. Pedicel with ovary, 20-35 mm long. Flower stellate to slightly campanulate, showy; dorsal sepals brown with white to yellow edges and apex, spathulate with basal auricles, then laminar, ovate, obtuse to acute, undulate, 13-24 × 11-12 mm; lateral sepals similar in color, spathulate with basal auricles, laminate, elongate ovate, obtuse to obliquely acute, 25-30 × 9-10 mm; petals similar in color, broadly spathulate, ovate, obtuse to acute, oblique, undulate, 23-24 × 10-13 mm; lip white with pale brown front-lobe, rigidly attached to the base of the column, cuneate, trilobate with erect, broadly linear and elongate, obliquely rounded side-lobes, and a narrowly triangular, ligulate, apically slightly convolute, obtuse to acute, recurved front-lobe, 22 × 22 mm; callus white, with three low and flattened, fleshy, longitudinal keels emerging from the base and extending to the front-lobe, then spreading, with the lateral pair ending in erect, laterally flattened angulate keels, and with an additional emerging pair of erect,
angular, laterally flattened, denticulate keels that are placed on each side of the rectangularly angulate central keel; column basally white with pale yellow on the ventral side, then brown, erect in a ca 90° angle from the base of the lip, slender and clavate, slightly sigmoid, with a slight swelling near the middle on the ventral side, with two parallel longitudinal keels below the stigma, where a pair of lateral, erect and falcate, slightly unequally bilobed to digitate and pointed wings emerge, ca. 11 mm long; anther cap yellow to purplish brown, campanulate with a pale green dorsal lobule; pollinarium of two pyriform, folded pollinia on a broadly obovate, slightly concave, ca. 1 mm long stipe, on a pulvinate viscidium.

**Eponymy:** Named in honor of Guido Deburghgraeve of Liedekerke, Belgium, whose support and contributions to the knowledge of Oncidiinae orchids has been substantial for many years.

**Cyrtochilum deburghgraeveanum** is similar to *C. cordatum* but differs in the rounded and white side-lobes of the lip versus pointed and brown to purple petals; dorsal sepals similar in color, spathulate with basal auricles, then laminate, broadly ovate, obtuse, widely undulate, 22-28 × ca. 15 mm; lateral sepals similar in color, spathulate with basal auricles, then laminate, broadly ovate, obtuse, widely undulate and slightly oblique, 27-28 × ca. 13 mm; petals basally whitish to pale pink, then with brown irregular mottling and a white apical third, shortly and broadly spathulate, then laminate, broadly ovate, obtuse, widely undulate, 21-23 × ca. 15 mm; lip yellowish brown with yellow around the callus, rigidly attached to the base of the column, cuneate, then hastate to cordate, trilobate with erect, obovate, weakly serratate and oblique side-lobes, and a narrowly triangular, ligulate, apically slightly convolute and recurved, acute to slightly acuminated front-lobe, ca. 22 × 22 mm; callus yellow, of three low, longitudinal keels, emerging from the base and extending to near the frontlobe, spreading, the lateral pair ends in raised, blunt, angulate keels, while the central keel continues with two new emerging, lateral, spreading keels on each side of the angular, nose-like apex; column basally pale yellow then brownish with brown wings with yellow edge, erect in an almost 90° angle from the basal part of the lip, slender and clavate, slightly sigmoid, with a slight swelling and two parallel short keels at the middle of the lip, slender and clavate, slightly sigmoid, with a slight swelling near the middle of the ventral side below the stigma, and with a pair of falcate, digitate wings on each side of the stigma, ca. 13 mm long; anther cap reddish brown, campanulate, with a pale green dorsal lobe; pollinarium of two pyriform, folded pollinia on a broadly rotund and slightly concave, ca. 1.5 mm long stipe, on a sepal ovate, pulvinate viscidium.

**Additional specimens seen:** Ecuador, Loja, “Rio Zenen”, color transparency by R. Thompson (Dalström photo archives).

**Eponymy:** Named in honor of Saul Ruiz Perez, a resident of Lima who collected the type plant and
who tirelessly continues to contribute knowledge of Peruvian orchids.

*Cyrtochilum ruizii* differs from both *C. deburghgraeveanum* and *C. cordatum* by the large and widely rounded, slightly spreading, unicolored brown lateral lobes of the lip, and by the attractive white petals, covered basally by a large brown blotch.

This apparently very rare species was previously known only from a color transparency, photographed some twenty-five years ago in a rather heavily deforested area north of Loja, Ecuador. No plant material ever surfaced. The second observation, and first known collection, constitutes the type of this species, which was found in a similarly deforested montane area in northern Peru. Only fractions of the rich and lush cloud forest that once covered the Peruvian Andes remain today, particularly in the northern regions. These remnants will, no doubt, be altogether gone within a few years. Fortunately, a few individual plants have been secured and artificial propagation will soon ensure the survival of this highly endangered and attractive orchid.

*Cyrtochilum ruizii* is similar to *Cyrtochilum cordatum* (Lindl.) Kraenzl., and *Cyrtochilum deburghgraeveanum* but is most easily distinguished by the brightly patterned petals, and the solid brown lip with a yellow callus.

*Cyrtochilum xanthocinctum* Dalström & S.Ruíz, sp. nov.

**TYPE:** Peru, Amazonas, Chachapoyas, Molinopampa, alt. ca 2400 m, collected by S. Ruíz in March 2011, S. Dalström 3450 (holotype, USM). **Fig. 3.**

*Cyrtoc* hilum *xanthocinctum* is only known from the heavily deforested area near the town of Molinopampa in northern Peru. Only small patches remain of the forest and the fate of this beautiful orchid is gloomy to say the least. Two plants were rescued from a scrubby patch of previously burnt vegetation and hopefully artificial propagation will ensure this spectacular species survival.

Although morphologically similar to the sympatric *Cyrtocilum macranthum* (Lindl.) Kraenzl., *Cyrtocilum xanthocinctum* is easily recognized by ovate, obtuse and apiculate, widely undulate, *ca.* 28 × 23 mm; *lateral sepals* similar in color, spathulate with basal auricles, then cordate laminate, ovate, rounded obtuse, widely undulate, 35 × 20 mm; *petals* basally white, then with a large brown blotch, bordered with yellow, broadly and shortly spathulate, then cordate laminate, ovate, rounded obtuse, densely undulate, 27 × 22 mm; *lip* basally pale lilac, then white, and then brown with a lighter apex, rigidly attached to the base of the column, cordate, trilobate with a pair of basal, erect and slightly incurved denticles, and widely spreading semi-erect and slightly concave, angular side-lobes, with or without additional erect minor denticles, and a narrowly triangular, ligulate, slightly recurved, acute frontlobe, 23 × 20 mm; callus whitish, of a fleshy central, longitudinal, low keel turning into an erect structure near the base of the front-lobe, similar to some strange aircraft with spreading double pairs of wings; *column* basally yellow then brown, stout, erect in a ca 90º angle from the base of the lip, slightly sigmoid, with a pair of parallel longitudinal ventral keels below the stigma, and with lateral, oblique obdeltoid, wine-red spreading wings, *ca.* 12 mm long; *anther cap* brown, campanulate, with a slight, purple dorsal lobule; *pollinarium* of two pyriform/globose cleft (or folded) pollinia on a broadly rotund, slightly concave *ca.* 1.5 mm long stipe on an oval, pulvinate viscidium.

**ADDITIONAL SPECIMENS SEEN:** Only a color transparency of a cultivated plant has been seen of this elusive and attractive species. The plant apparently died shortly after the photo was taken.

**ETYMOLOGY:** In reference to the attractive yellow borders of the petals.

---

**Cyrtocilum macranthum** Lindl. *similis, sed colore petalibus, lobulis lateralibus et callo labelli differt.*

Epiphytic *herb. Pseudobulbs* caespitose, broadly ovoid, *ca.* 7.5 × 4.5 cm, bifoliolate, surrounded basally by 4 to 6 distichous, sheaths, the uppermost foliaceous. *Leaves* subpetiolate, conduplicate, obovate, acute, 13-17 × *ca.* 3.5 cm. *Inflorescence* axillary, from the uppermost sheaths, erect then wiry, to ca 150 cm long. *Bracts* large and conspicuous, involute cucullate, *ca.* 10-15 mm long. *Pedicel* with *ovary* ca. 5 cm long. *Flower* stellate and showy; *dorsal sepal* brown, spathulate with basal auricles, then cordate laminate, broadly
the brown petals with strikingly contrasting yellow borders. Also the lateral callus keels on the lip are more laterally spreading in our new species.

ACKNOWLEDGMENTS. The authors thank the staff at the Instituto Recursos Naturales (INRENA), and Betty Millán at the Universidad de San Marcos, Museo de Historia Natural, Lima, for aiding in providing the necessary permits. We thank Wesley Higgins and Franco Pupulin for assistance with the manuscript, Ricardo Fernández for assistance at the USM herbarium, and a gracious thank you to Manolo Arias, his family and staff for generous logistic support. All plant material involved in this article was acquired in accordance with collecting permit 0283-2010-AG-DGFFS-DGEFFS.
