SUMMARY

The proximate composition of meat and carcass characteristics of twenty-four (24) growing pigs fed graded levels of a microbially enhanced cassava peel diets were assessed in a trial that lasted three months. The cassava peels were fermented with a consortium of *Aspergillus fumigatus* (a fungus) and two lactic acid bacteria namely, *Lactobacillus coryneformis* and *Lactobacillus delbrueckii*, thus the fermented product was designated Microbially Enhanced Cassava Peel (MECP). The MECP was included in the ration formulation of the pigs at 0%, 20%, 40% and 60% levels. At slaughter, meat samples were collected from the M. *biceps femoris* to determine their proximate composition and the weights of the head, viscera and back fat thickness at the 1st and 10th ribs and 1st lumbar vertebra were taken.

The results obtained revealed significant differences ($p < 0.05$) in proximate meat composition and carcass characteristics between animals fed on the control diet and those fed on varying levels of MECP diets. The treatment effect showed that animals raised on MECP with 60% level of inclusion had the highest (15.09%) muscle protein. The female animals had significantly ($p < 0.05$) higher dry matter, ash, protein and fat content while the males had a higher moisture content in their M. *biceps femoris* muscle. The sex versus treatment effect revealed the female animals on 60% MECP had the least (69.21%) moisture content while the male animals on 40% MECP had the highest (75.42%). Muscle protein was highest in animals fed 20% MECP while the female animals on 60%

MECP had the highest (13.86%) level of muscular fat. The female animals had thicker back fat at the 1st and 10th ribs and at the 1st lumbar vertebra. Ash content of the muscle increased as the level of inclusion of MECP in the diets increased also animals fed MECP diets had the leanest carcasses.

It can be concluded that feeding pigs with 40% dietary level of MECP would ensure carcass leanness and improve protein and dry matter content of pig's meat.

RESUMEN

La composición de la carne y las características de la canal de 24 cerdos en crecimiento, alimentados con una dieta a base de peladuras de yuca mejoradas microbiológicamente fueron analizadas en un experimento que duró tres meses. Las peladuras de yuca fueron fermentadas con una asociación del hongo *Aspergillus fumigatus* y dos bacterias lácticas: *Lactobacillus coryneformis* y *Lactobacillus delbrueckii*. El producto fermentado fue denominado Peladuras de Yuca Microbiológicamente Mejoradas (MECP). El MECP fue incluido en las raciones de los cerdos a las proporciones de 0%, 20%, 40% y 60%. En el momento del sacrificio fueron obtenidas muestras del *Musculus biceps femoris* para determinar su composición así como los pesos de cabeza, vísceras y espesor de la grasa dorsal a la altura de las 1^a y 10^a costillas y 1^a vértebra lumbar.

Los resultados obtenidos revelaron diferencias significativas ($p < 0.05$) en la composición de

Recibido: 31-1-11. Aceptado: 23-2-12.

Arch. Zootec. 61 (235): 407-414. 2012.

la carne y características de la canal entre los animales control y los alimentados con MECP. El efecto de los tratamientos demostró que los animales alimentados con 60% de MECP alcanzaron el mayor nivel de proteína muscular (15,09%). Las hembras, tuvieron mayor ($p < 0,05$) concentración de materia seca, cenizas, proteína y grasas, mientras que los machos tenían mayor contenido de humedad en el *Biceps femoris*. El efecto del sexo vs. tratamiento puso de manifiesto que las hembras con 60% de MECP tienen el menor contenido de humedad (69,21%) mientras que los machos con 40% MECP tuvieron el contenido más alto (75,42%). La proteína muscular fue más elevada en los animales alimentados con 20% de MECP, mientras que las hembras alimentadas con 60% MECP tuvieron el nivel más alto de grasa muscular (13,86%). Las hembras tuvieron mayor grosor de la grasa dorsal a la altura de las 1ª y 10ª costillas y 1ª vértebra lumbar. La concentración de cenizas en el músculo aumentó con el nivel de inclusión de MECP en la dieta. También los animales consumiendo dietas con MECP mostraron canales más magras. Puede concluirse que la alimentación de cerdos con un 40% de MECP en la dieta, asegura canales magras y mejora el nivel de proteína y materia seca de la carne de cerdo.

INTRODUCTION

As a palliative to the high cost of conventional feed ingredients, many unconventional feed sources have been tried by researchers to reduce feed cost and ensure the profitability of the livestock enterprise especially in developing countries where scarcity of the conventional ingredients is a perennial problem (Onimisi and Omeje, 2006; Owen *et al.*, 2009). Many of these unconventional ingredients are agro-industrial by-products of such crops like rice, maize, groundnut, soybean, oil palm and cassava. Recently in Nigeria, the government legislated in favour of the use of 10% cassava flour in the pastry and confectionery industry as a way of encouraging the production and utilization of cassava products in the country. Many cassava flour processing plants thus sprang up to take advantage of this initiative by the

government. The attendant effect of this is the huge quantity of cassava tuber wastes that are being discharged into the environment on a daily basis (Aro *et al.*, 2010b). These agro-industrial by-products have the potentials of being utilized as alternative feed ingredients but are however constrained by low protein content, high fibre content and high levels of feed anti-nutrients (D'Mello, 1995; Udedibia *et al.*, 2004). Efforts have been made to enhance the utilization of these wastes in livestock ration through many nutrient-enhancing methods (Aro *et al.*, 2009; Aro *et al.*, 2010a).

The potential use of these unconventional feed ingredients has often been measured by performance indicators like weight gain, feed conversion ratio, feed efficiency and feed cost/kilogramme weight gain. Of much importance to the health and sensory appeal of the consumers of animal products on one hand and the producers of the products on the other hand are such carcass indices like fat content, protein content, carcass yield and the lean to fat ratio of the carcass of animals fed with these unconventional feed ingredients. For instance, Sarker *et al.* (2010) reported that besides human consumption, the low grade green tea and green tea wastes (unconventional feed ingredients from tea) were used as feed ingredients for fish, broiler, calves and pigs. These authors showed that pigs fed graded levels of green tea in their diets had thinner back fat, higher protein and moisture and lower crude fat in their carcasses. Isah *et al.* (2009) also reported an increased level of crude protein and a decrease in fat content of the *Longissimus dorsi* muscle of West African Dwarf (WAD) goats fed slaughter house by-products. The effect of dietary replacement of fish meal with dried poultry waste in broilers diets was investigated by Oke *et al.* (2010) with a conclusion that dietary poultry waste resulted in better carcass weight of the choice regions like the breast and drumstick and suggested that half of the required fish

meal by broilers could be replaced with dried poultry dropping meal.

The effect of the use of fermented sweet orange peel on carcass quality of broilers was investigated by Oluremi *et al.* (2010). These authors reported a significant effect on the birds dressing percentage and concluded that 30% replacement of maize with naturally fermented sweet orange peel meal is practicable in broiler production enterprise. Fermented cassava products have also been used severally as alternative feed sources for many livestock species with cost-reducing benefits (Udedibie *et al.*, 2004; Ekpo *et al.*, 2009). There is however little information on the effects of the use of microbially fermented cassava wastes on meat quality and carcass characteristics of farm animals and especially of pigs. The objective of this research work was to investigate the effect of feeding cassava peels fermented with candidate organisms on proximate meat composition and carcass characteristics of pigs.

MATERIAL AND METHODS

Twenty-four cross-bred pigs (Large White x Duroc) with an average initial weight of 31.23 kg were used to study the effects of graded levels of microbially enhanced cassava peels (MECP) on proximate meat composition and carcass characteristics. The MECP were prepared according to the methods described by Aro *et al.* (2008). Briefly: the cassava peels were sundried for three to five days depending on environmental temperature and the intensity of the sun. They were thereafter crushed to aid further processing, packed and stored in a cool place prior to inoculation with microorganisms. Two different strains of lactic acid bacteria (*Lactobacillus delbrueckii* and *Lactobacillus coryneformis*) and a fungus (*Aspergillus fumigatus*) were isolated and cultured at the Department of Microbiology, Federal University of Technology, Akure. Two kilogrammes (2

kg) of dried cassava peels were weighed into nylon bags and 1500 mL of sterile water were added. The samples were then steam-heated for 30 minutes at 100°C. The samples were allowed to cool after which they were emptied into fermentation trays overlaid with cellophane wrapper inside the lamina flow chamber. Each 2 kg sample was then inoculated with 15 mL each of *L. delbrueckii* and *L. coryneformis* containing 1.02×10^4 cells/mL, and 30 mL of *Aspergillus fumigatus* containing 1.07×10^7 spores/mL. The trays were then covered with cellophane wrapper and kept in fermentation chamber for five days under ambient temperature and controlled humidity ensured by the cellophane wrapper technique meant to maintain optimum water activity (figures 1 and 2). After the fifth day, the samples were harvested and sundried for three or more days prior to their incorporation into the diets of the pigs.

Four pigs' growers' diets were formulated in which the MECP meal was incorporated at 0%, 20%, 40% and 60% levels (table I). The pigs were randomly allotted to these four treatment diets at six animals (three males and three females) per treatment with each animal serving as a replicate of its treatment group. The animals were housed in individual pens measuring 2 x 3 m each fitted with a concretized feeding and drinking trough. Feeding was at 5% of the pigs' body weight which was adjusted weekly to reflect change in weight while water was given *ad libitum* throughout twelve week duration of the experiment. At the end of the twelfth week, the animal were starved of feed overnight, weighed and taken to the slaughter slab at 07 hours the following morning where they were stunned, bled, scalded, de-haired and dressed. The *biceps femoris* was neatly dissected from the right thigh musculature of the warm carcass of each animal from which 20 g samples were taken for proximate analysis. Measurement of the back fat thickness was taken (with a flexible measuring tape graduated to 1 mm) at the

Proximate analyses were carried out for moisture, crude protein, ether extract and ash of the meat samples as described by the methods of AOAC (1996). Data obtained on the proximate composition of the muscle and carcass parameters were subjected statistical analysis using the SAS (2000)

statistical package. Mean separation where applicable was done with the same statistical package.

RESULTS AND DISCUSSION

Table II shows the proximate analysis of the *biceps femoris* muscle (fresh weight basis) taken from the experimental animals. The effect of sex showed that fat, protein, ash and dry matter were higher in the female than in the male pigs while the males had higher moisture content. The treatment effect revealed that animals fed 40% MECP had highest ash and moisture but with the lowest fat content while the highest dry matter, protein and fat were observed in the animals fed 60% MECP. Generally, ash and protein were improved by the dietary inclusion of MECP. Sex versus treatment effect showed that female animals on 40% MECP had more mineralization (4.81%) and less lipogenesis (8.34%) of their musculature while their male

counterparts had the least (7.25%) fat and the highest (75.42%) moisture content. Sarker *et al.* (2010), working on an unconventional feed ingredient: green tea, reported decreased lipogenesis, increased protein accretion and decrease in ash content of the muscle in pigs fed dietary inclusion of green tea. The increase in ash content of the muscle in this study could have been caused by the process of fermentation which the cassava peels underwent with improved mineralization of the fermented product (MECP) which ultimately furnish more minerals that are incorporated into the tissue upon absorption. The moisture content of the muscle increased with dietary inclusion of MECP in the males while it decreased in the females. Protein increased progressively in muscle of the male animals in relation to increase in the levels of dietary MECP. In the female, it increased initially at 20% MECP

level from where it declined but with numerical values still higher than that of the control diet. Sarker *et al.* (2010) obtained similar trend with dietary green tea with pigs whose muscle protein initially increased but later decline at 2% inclusion level. The dry matter content of the muscle in the female animals also increased progressively from 20% MECP to 60% MECP while in the males the ash content improved from 20% MECP but decline below the value of the control treatment at 60% MECP level.

The carcass parameters of pigs fed varying levels of MECP are as shown in **table III**. Observation on the effect of sex showed that the female animals had numerically heavier slaughter weight, deeper back fat, heavier head and heavier weight of the viscera organs but lower dressing percentage. The dressing percentage values however compared with literature values on

growing pigs (Estany *et al.*, 2002; Carr *et al.*, 2005; Matthews *et al.*, 2005). The values obtained for back fat thickness at the 1st rib between the sexes were lower than 3.51-4.00 cm reported by Carr *et al.* (2005) and this showed that the animals under this study were leaner. The back fat thickness at the 10th rib obtained in this study was slightly higher than between 1.49 cm to 1.54 cm reported by Matthew *et al.* (2005) but compared with 1.58 cm to 2.07 cm reported by Carr *et al.* (2005). The effect of dietary treatments on carcass parameters revealed that the best dressing percentage was observed in animals fed 40% dietary inclusion of MECP. There was a corresponding improvement in carcass leanness as the level of MECP increased in the diets as reflected in the values of back fat thickness at the 1st and 10th rib and the 1st

lumbar vertebra. The effect of sex versus treatment showed that the male animals on 40% MECP had the heaviest (74.12 kg) slaughter weight among the male animals while the female animals on 0% MECP had the heaviest (92.12 kg). Dressing percentage increased with increasing levels of MECP among the males while the 40% MECP level recorded the best dressing percentage (75.59%) in both sexes.

CONCLUSION

This study revealed potential benefits that could be harnessed through the use of microbially enhanced cassava peel (MECP) in terms of meeting the demand of consumers for carcass leanness especially among those watching their weights and those at risk of hypercholesterolaemia and hyperlipaemia. The higher dressing percentage recorded in

MEAT AND CARCASS OF PIGS FED MICROBIALY ENHANCED CASSAVA PEEL DIETS

pigs fed with 40% MECF diet would also indicate more saleable cuts per kilogramme carcass weight upon slaughter. The consumers would also benefit from more protein and mineral contents of the meat.

The utilisation of MECF at 40% level is recommended for optimal effects in terms of higher dressing percentage and proximate meat composition as far as this trial is concerned.
