The main aim of the study was to know the relationships between parents and children with regard to perception of intention, performance and judgment of antisocial behaviors in the sport context, assessing in the same sport action, the morality shown by both significatives. The sample comprised 1420 participants, 710 athletes, ranging in age from 11 to 16 years old ($M = 12.76$; $SD = 1.15$), and 710 parents, ranging in age from 36 to 49 years old ($M = 43.56$; $SD = 2.95$). Athletes and parents completed questionnaires related to measure perception of players and parents about antisocial behaviors, as well as perception of motivational climate developed by parents. Results showed a significant relationship among antisocial variables in parents and children. Moreover, parents pressure emerged as predictor of intention and performance of antisocial behaviors. Finally, it is emphasized that appropriate parental participation in sport practice can promote the decrease of antisocial behaviors in athletes.
